14.14.1.1 CTRLR0 — Offset 48100000h

Control Register 0 - This register controls the serial data transfer. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: SSI_CTRLR0_RST

Type	Size	Offset	Default
MMIO	32 bit	48100000h	01000007h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:25	0h RO	**Reserved**
24	1h RW	**SSTE:** Slave Select Toggle Enable. When operating in SPI mode with clock phase (SCPH) set to 0, this register controls the behavior of the slave select line (ss_*_n) between data frames. If this register field is set to 1 the ss_*_n line will toggle between consecutive data frames, with the serial clock (sclk) being held to its default value while ss_*_n is high; if this register field is set to 0 the ss_*_n will stay low and sclk will run continuously for the duration of the transfer. Note: This register is only valid when SSI_SCPH0_SSTOGGLE is set to 1.
23	0h RO	**Reserved**
22:21	0h RO/V	**SPI_FRF:** SPI Frame Format: Selects data frame format for Transmitting/Receiving the data Bits only valid when SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode. When SSI_SPI_MODE is configured for "Dual Mode", 10/11 combination is reserved. When SSI_SPI_MODE is configured for "Quad Mode", 11 combination is reserved.
20:16	00h RO/V	**DFS_32:** Data Frame Size in 32-bit transfer size mode. Used to select the data frame size in 32-bit transfer mode. These bits are only valid when SSI_MAX_XFER_SIZE is configured to 32. When the data frame size is programmed to be less than 32 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You are responsible for making sure that transmit data is right-justified before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 0x01, - DFS value should be multiple of 4 if SPI_FRF = 0x10, - DFS value should be multiple of 8 if SPI_FRF = 0x11.
15:12	0h RW	**CFS:** Control Frame Size. Selects the length of the control word for the Microwire frame format.
11	0h RW	**SRL:** Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. Can be used in both serial-slave and serial-master modes. When the DW_apb_ssi is configured as a slave in loopback mode, the ss_in_n and ssi_clk signals must be provided by an external source. In this mode, the slave cannot generate these signals because there is nothing to which to loop back
10	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
9:8	0h RW	**TMOD:** Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. In eeprom-read mode, receive data is not valid while control data is being transmitted. When all control data is sent to the EEPROM, receive data becomes valid and transmit data becomes invalid. All data in the transmit FIFO is considered control data in this mode. This transfer mode is only valid when the DW_apb_ssi is configured as master device. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - EEPROM Read When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. There are only two valid combinations: 10 - Read 01 - Write
7	0h RW	**SCPOL:** Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus.
6	0h RW	**SCPH:** Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock.
5:4	0h RW	**FRF:** Frame Format. Selects which serial protocol transfers the data.
3:0	7h RW	**DFS:** Data Frame Size. This register field is only valid when SSI_MAX_XFER_SIZE is configured to 16. If SSI_MAX_XFER_SIZE is configured to 32, then writing to this field will not have any effect. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 01, - DFS value should be multiple of 4 if SPI_FRF = 10, - DFS value should be multiple of 8 if SPI_FRF = 11.

14.14.1.2 CTRLR1 — Offset 48100004h

Control Register 1 - This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

15:0	0000h RW	**NDF:** Number of Data Frames. When TMOD = 10 or TMOD = 11 , this register field sets the number of data frames to be continuously received by the DW_apb_ssi. The DW_apb_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When the DW_apb_ssi is configured as a serial slave, the transfer continues for as long as the slave is selected. Therefore, this register serves no purpose and is not present when the DW_apb_ssi is configured as a serial slave.

Transmit and receive FIFO buffers are cleared when the device is disabled. It is impossible to program some of the DW_apb_ssi control registers when enabled. When disabled, the ssi_sleep output is set (after delay) to inform the system that it is safe to remove the ssi_clk, thus saving power consumption in the system.

Used to enable and disable the busy/ready handshaking interface for the Microwire protocol. When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register.
1	0h RW	**MDD:** Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device.
0	0h RW	**MWMOD:** Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received.

14.14.1.25 DR0 — Offset 48100060h

Data Register x - The DW_apb_ssi data register is a 16/32-bit (depending on SSI_MAX_XFER_SIZE) read/write buffer for the transmit/receive FIFOs. If the configuration parameter SSI_MAX_XFER_SIZE is set to 32, then all 32 bits are valid, otherwise, only 16 bits ([15:0]) of the register are valid. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. NOTE: The DR register in the DW_apb_ssi occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the pwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable. Reset Value: 0x0

31:16	0h RO	**Reserved**
15:0	0000h RW/V	**DR:** Data Register. When writing to this register, you must right-justify the data. Read data are automatically right-justified. If SSI_MAX_XFER_SIZE configuration parameter is set to 32, all 32 bits are valid. Otherwise, only 16 bits ([15:0]) of the register are valid. Read = Receive FIFO buffer Write = Transmit FIFO buffer.

14.14.1.26 DR1 — Offset 48100064h

Data Register x - The DW_apb_ssi data register is a 16/32-bit (depending on SSI_MAX_XFER_SIZE) read/write buffer for the transmit/receive FIFOs. If the configuration parameter SSI_MAX_XFER_SIZE is set to 32, then all 32 bits are valid, otherwise, only 16 bits ([15:0]) of the register are valid. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. NOTE: The DR register in the DW_apb_ssi occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the pwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable. Reset Value: 0x0

Note: Bit definitions are the same as DR0, offset 48100060h.

14.14.1.51 DR26 — Offset 481000C8h

Data Register x - The DW_apb_ssi data register is a 16/32-bit (depending on SSI_MAX_XFER_SIZE) read/write buffer for the transmit/receive FIFOs. If the configuration parameter SSI_MAX_XFER_SIZE is set to 32, then all 32 bits are valid, otherwise, only 16 bits ([15:0]) of the register are valid. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. NOTE: The DR register in the DW_apb_ssi occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the pwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable. Reset Value: 0x0

RX Sample Delay Register - This register is only valid when the DW_apb_ssi is configured with rxd sample delay logic (SSI_HAS_RX_SAMPLE_DELAY==1). When the DW_apb_ssi is not configured with rxd sample delay logic, this register will not exist and writing to its address location will have no effect; reading from its address will return zero. This register control the number of ssi_clk cycles that are delayed (from the default sample time) before the actual sample of the rxd input occurs. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

31:25	0h RO	**Reserved**
24	1h RW	**SSTE:** Slave Select Toggle Enable. When operating in SPI mode with clock phase (SCPH) set to 0, this register controls the behavior of the slave select line (ss_*_n) between data frames. If this register field is set to 1 the ss_*_n line will toggle between consecutive data frames, with the serial clock (sclk) being held to its default value while ss_*_n is high; if this register field is set to 0 the ss_*_n will stay low and sclk will run continuously for the duration of the transfer. Note: This register is only valid when SSI_SCPH0_SSTOGGLE is set to 1.
23	0h RO	**Reserved**
22:21	0h RO/V	**SPI_FRF:** SPI Frame Format: Selects data frame format for Transmitting/Receiving the data Bits only valid when SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode. When SSI_SPI_MODE is configured for "Dual Mode", 10/11 combination is reserved. When SSI_SPI_MODE is configured for "Quad Mode", 11 combination is reserved.
20:16	00h RO/V	**DFS_32:** Data Frame Size in 32-bit transfer size mode. Used to select the data frame size in 32-bit transfer mode. These bits are only valid when SSI_MAX_XFER_SIZE is configured to 32. When the data frame size is programmed to be less than 32 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You are responsible for making sure that transmit data is right-justified before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 0x01, - DFS value should be multiple of 4 if SPI_FRF = 0x10, - DFS value should be multiple of 8 if SPI_FRF = 0x11.
15:12	0h RW	**CFS:** Control Frame Size. Selects the length of the control word for the Microwire frame format.
11	0h RW	**SRL:** Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. Can be used in both serial-slave and serial-master modes. When the DW_apb_ssi is configured as a slave in loopback mode, the ss_in_n and ssi_clk signals must be provided by an external source. In this mode, the slave cannot generate these signals because there is nothing to which to loop back
10	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
9:8	0h RW	**TMOD:** Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. In eeprom-read mode, receive data is not valid while control data is being transmitted. When all control data is sent to the EEPROM, receive data becomes valid and transmit data becomes invalid. All data in the transmit FIFO is considered control data in this mode. This transfer mode is only valid when the DW_apb_ssi is configured as master device. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - EEPROM Read When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. There are only two valid combinations: 10 - Read 01 - Write
7	0h RW	**SCPOL:** Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus.
6	0h RW	**SCPH:** Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock.
5:4	0h RW	**FRF:** Frame Format. Selects which serial protocol transfers the data.
3:0	7h RW	**DFS:** Data Frame Size. This register field is only valid when SSI_MAX_XFER_SIZE is configured to 16. If SSI_MAX_XFER_SIZE is configured to 32, then writing to this field will not have any effect. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 01, - DFS value should be multiple of 4 if SPI_FRF = 10, - DFS value should be multiple of 8 if SPI_FRF = 11.

When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register.
1	0h RW	**MDD:** Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device.
0	0h RW	**MWMOD:** Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received.

14.14.2.5 SER — Offset 48102010h

Slave Enable Register - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register enables the individual slave select output lines from the DW_apb_ssi master. Up to 16 slave-select output pins are available on the DW_apb_ssi master. Register bits can be set or cleared when SSI_EN=0. If SSI_EN=1, then register bits can be set (to delay the slave select assertion while TX FIFO is getting filled) but cannot be cleared. Reset Value: 0x0

31:2	0h RO	**Reserved**
1:0	0h RW	**SER:** Slave Select Enable Flag. Each bit in this register corresponds to a slave select line (ss_x_n) from the DW_apb_ssi master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set.

14.14.2.6 BAUDR — Offset 48102014h

Baud Rate Select - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the ssi_clk divider value. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

If the value is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation: Fsclk_out = Fssi_clk/SCKDV where SCKDV is any even value between 2 and 65534. For example: for Fssi_clk = 3.6864MHz and SCKDV =2 Fsclk_out = 3.6864/2 = 1.8432MHz

Data Register x - The DW_apb_ssi data register is a 16/32-bit (depending on SSI_MAX_XFER_SIZE) read/write buffer for the transmit/receive FIFOs. If the configuration parameter SSI_MAX_XFER_SIZE is set to 32, then all 32 bits are valid, otherwise, only 16 bits ([15:0]) of the register are valid. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. NOTE: The DR register in the DW_apb_ssi occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the pwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable. Reset Value: 0x0

Note: Bit definitions are the same as DR0, offset 48102060h.

14.14.2.61 RX_SAMPLE_DLY — Offset 481020F0h

RX Sample Delay Register - This register is only valid when the DW_apb_ssi is configured with rxd sample delay logic (SSI_HAS_RX_SAMPLE_DELAY==1). When the DW_apb_ssi is not configured with rxd sample delay logic, this register will not exist and writing to its address location will have no effect; reading from its address will return zero. This register control the number of ssi_clk cycles that are delayed (from the default sample time) before the actual sample of the rxd input occurs. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

31:25	0h RO	**Reserved**
24	1h RW	**SSTE:** Slave Select Toggle Enable. When operating in SPI mode with clock phase (SCPH) set to 0, this register controls the behavior of the slave select line (ss_*_n) between data frames. If this register field is set to 1 the ss_*_n line will toggle between consecutive data frames, with the serial clock (sclk) being held to its default value while ss_*_n is high; if this register field is set to 0 the ss_*_n will stay low and sclk will run continuously for the duration of the transfer. Note: This register is only valid when SSI_SCPH0_SSTOGGLE is set to 1.
23	0h RO	**Reserved**
22:21	0h RO/V	**SPI_FRF:** SPI Frame Format: Selects data frame format for Transmitting/Receiving the data Bits only valid when SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode. When SSI_SPI_MODE is configured for "Dual Mode", 10/11 combination is reserved. When SSI_SPI_MODE is configured for "Quad Mode", 11 combination is reserved.
20:16	00h RO/V	**DFS_32:** Data Frame Size in 32-bit transfer size mode. Used to select the data frame size in 32-bit transfer mode. These bits are only valid when SSI_MAX_XFER_SIZE is configured to 32. When the data frame size is programmed to be less than 32 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You are responsible for making sure that transmit data is right-justified before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 0x01, - DFS value should be multiple of 4 if SPI_FRF = 0x10, - DFS value should be multiple of 8 if SPI_FRF = 0x11.
15:12	0h RW	**CFS:** Control Frame Size. Selects the length of the control word for the Microwire frame format.
11	0h RW	**SRL:** Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. Can be used in both serial-slave and serial-master modes. When the DW_apb_ssi is configured as a slave in loopback mode, the ss_in_n and ssi_clk signals must be provided by an external source. In this mode, the slave cannot generate these signals because there is nothing to which to loop back
10	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
9:8	0h RW	**TMOD:** Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. In eeprom-read mode, receive data is not valid while control data is being transmitted. When all control data is sent to the EEPROM, receive data becomes valid and transmit data becomes invalid. All data in the transmit FIFO is considered control data in this mode. This transfer mode is only valid when the DW_apb_ssi is configured as master device. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - EEPROM Read When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. There are only two valid combinations: 10 - Read 01 - Write
7	0h RW	**SCPOL:** Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus.
6	0h RW	**SCPH:** Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock.
5:4	0h RW	**FRF:** Frame Format. Selects which serial protocol transfers the data.
3:0	7h RW	**DFS:** Data Frame Size. This register field is only valid when SSI_MAX_XFER_SIZE is configured to 16. If SSI_MAX_XFER_SIZE is configured to 32, then writing to this field will not have any effect. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 01, - DFS value should be multiple of 4 if SPI_FRF = 10, - DFS value should be multiple of 8 if SPI_FRF = 11.

14.14.3.2 CTRLR1 — Offset 48104004h

Control Register 1 - This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

15:0	0000h RW	**NDF:** Number of Data Frames. When TMOD = 10 or TMOD = 11 , this register field sets the number of data frames to be continuously received by the DW_apb_ssi. The DW_apb_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When the DW_apb_ssi is configured as a serial slave, the transfer continues for as long as the slave is selected. Therefore, this register serves no purpose and is not present when the DW_apb_ssi is configured as a serial slave.

Transmit and receive FIFO buffers are cleared when the device is disabled. It is impossible to program some of the DW_apb_ssi control registers when enabled. When disabled, the ssi_sleep output is set (after delay) to inform the system that it is safe to remove the ssi_clk, thus saving power consumption in the system.

Microwire Control Register - This register controls the direction of the data word for the half-duplex Microwire serial protocol. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

2	0h RW	**MHS:** Microwire Handshaking. Relevant only when the DW_apb_ssi is configured as a serial-master device. When configured as a serial slave, this bit field has no functionality. Used to enable and disable the busy/ready handshaking interface for the Microwire protocol. When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register.
1	0h RW	**MDD:** Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device.
0	0h RW	**MWMOD:** Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received.

14.14.3.5 SER — Offset 48104010h

Slave Enable Register - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register enables the individual slave select output lines from the DW_apb_ssi master. Up to 16 slave-select output pins are available on the DW_apb_ssi master. Register bits can be set or cleared when SSI_EN=0. If SSI_EN=1, then register bits can be set (to delay the slave select assertion while TX FIFO is getting filled) but cannot be cleared. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set.

14.14.3.6 BAUDR — Offset 48104014h

Baud Rate Select - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the ssi_clk divider value. Status Register - This is a read-only register used to indicate the current transfer status, FIFO status, and any transmission/reception errors that may have occurred. The status register may be read at any time. None of the bits in this register request an interrupt. Reset Value: 0x6

Type	Size	Offset	Default
MMIO	32 bit	48104028h	00000006h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**DCOL:** Data Collision Error. Relevant only when the DW_apb_ssi is configured as a master device. This bit will be set if ss_in_n input is asserted by other master, when the DW_apb_ssi master is in the middle of the transfer. This informs the processor that the last data transfer was halted before completion. This bit is cleared when read.
5	0h RO	**Reserved**
4	0h RO/V	**RFF:** Receive FIFO Full. When the receive FIFO is completely full, this bit is set. When the receive FIFO contains one or more empty location, this bit is cleared.
3	0h RO/V	**RFNE:** Receive FIFO Not Empty. Set when the receive FIFO contains one or more entries and is cleared when the receive FIFO is empty. This bit can be polled by software to completely empty the receive FIFO.
2	1h RO/V	**TFE:** Transmit FIFO Empty. When the transmit FIFO is completely empty, this bit is set. When the transmit FIFO contains one or more valid entries, this bit is cleared. This bit field does not request an interrupt.
1	1h RO/V	**TFNF:** Transmit FIFO Not Full. Set when the transmit FIFO contains one or more empty locations, and is cleared when the FIFO is full.
0	0h RO/V	**BUSY:** SSI Busy Flag. When set, indicates that a serial transfer is in progress; when cleared indicates that the DW_apb_ssi is idle or disabled.

14.14.3.12 IMR — Offset 4810402Ch

Interrupt Mask Register - This read/write reigster masks or enables all interrupts generated by the DW_apb_ssi. When the DW_apb_ssi is configured as a slave device, the MSTIM bit field is not present. This changes the reset value from 0x3F for serial-master configurations to 0x1F for serial-slave configurations. Reset Value: (SSI_IS_MASTER == 1) ? 0x3F : 0x1F

14.14.3.38 DR13 — Offset 48104094h

Data Register x - The DW_apb_ssi data register is a 16/32-bit (depending on SSI_MAX_XFER_SIZE) read/write buffer for the transmit/receive FIFOs. If the configuration parameter SSI_MAX_XFER_SIZE is set to 32, then all 32 bits are valid, otherwise, only 16 bits ([15:0]) of the register are valid. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. NOTE: The DR register in the DW_apb_ssi occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the pwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable. Reset Value: 0x0

14.14.3.61 RX_SAMPLE_DLY — Offset 481040F0h

RX Sample Delay Register - This register is only valid when the DW_apb_ssi is configured with rxd sample delay logic (SSI_HAS_RX_SAMPLE_DELAY==1). When the DW_apb_ssi is not configured with rxd sample delay logic, this register will not exist and writing to its address location will have no effect; reading from its address will return zero. This register control the number of ssi_clk cycles that are delayed (from the default sample time) before the actual sample of the rxd input occurs. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

31:25	0h RO	**Reserved**
24	1h RW	**SSTE:** Slave Select Toggle Enable. When operating in SPI mode with clock phase (SCPH) set to 0, this register controls the behavior of the slave select line (ss_*_n) between data frames. If this register field is set to 1 the ss_*_n line will toggle between consecutive data frames, with the serial clock (sclk) being held to its default value while ss_*_n is high; if this register field is set to 0 the ss_*_n will stay low and sclk will run continuously for the duration of the transfer. Note: This register is only valid when SSI_SCPH0_SSTOGGLE is set to 1.
23	0h RO	**Reserved**
22:21	0h RO/V	**SPI_FRF:** SPI Frame Format: Selects data frame format for Transmitting/Receiving the data Bits only valid when SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode. When SSI_SPI_MODE is configured for "Dual Mode", 10/11 combination is reserved. When SSI_SPI_MODE is configured for "Quad Mode", 11 combination is reserved.
20:16	00h RO/V	**DFS_32:** Data Frame Size in 32-bit transfer size mode. Used to select the data frame size in 32-bit transfer mode. These bits are only valid when SSI_MAX_XFER_SIZE is configured to 32. When the data frame size is programmed to be less than 32 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You are responsible for making sure that transmit data is right-justified before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 0x01, - DFS value should be multiple of 4 if SPI_FRF = 0x10, - DFS value should be multiple of 8 if SPI_FRF = 0x11.
15:12	0h RW	**CFS:** Control Frame Size. Selects the length of the control word for the Microwire frame format.
11	0h RW	**SRL:** Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. Can be used in both serial-slave and serial-master modes. When the DW_apb_ssi is configured as a slave in loopback mode, the ss_in_n and ssi_clk signals must be provided by an external source. In this mode, the slave cannot generate these signals because there is nothing to which to loop back
10	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
9:8	0h RW	**TMOD:** Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. In eeprom-read mode, receive data is not valid while control data is being transmitted. When all control data is sent to the EEPROM, receive data becomes valid and transmit data becomes invalid. All data in the transmit FIFO is considered control data in this mode. This transfer mode is only valid when the DW_apb_ssi is configured as master device. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - EEPROM Read When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. There are only two valid combinations: 10 - Read 01 - Write
7	0h RW	**SCPOL:** Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus.
6	0h RW	**SCPH:** Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock.
5:4	0h RW	**FRF:** Frame Format. Selects which serial protocol transfers the data.
3:0	7h RW	**DFS:** Data Frame Size. This register field is only valid when SSI_MAX_XFER_SIZE is configured to 16. If SSI_MAX_XFER_SIZE is configured to 32, then writing to this field will not have any effect. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data Note: When SSI_SPI_MODE is either set to "Dual" or "Quad" or "Octal" mode and SPI_FRF is not set to 2'b00. - DFS value should be multiple of 2 if SPI_FRF = 01, - DFS value should be multiple of 4 if SPI_FRF = 10, - DFS value should be multiple of 8 if SPI_FRF = 11.

Control Register 1 - This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

15:0	0000h RW	**NDF:** Number of Data Frames. When TMOD = 10 or TMOD = 11 , this register field sets the number of data frames to be continuously received by the DW_apb_ssi. The DW_apb_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When the DW_apb_ssi is configured as a serial slave, the transfer continues for as long as the slave is selected. Therefore, this register serves no purpose and is not present when the DW_apb_ssi is configured as a serial slave.

Transmit and receive FIFO buffers are cleared when the device is disabled. It is impossible to program some of the DW_apb_ssi control registers when enabled. When disabled, the ssi_sleep output is set (after delay) to inform the system that it is safe to remove the ssi_clk, thus saving power consumption in the system.

Microwire Control Register - This register controls the direction of the data word for the half-duplex Microwire serial protocol. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

2	0h RW	**MHS:** Microwire Handshaking. Relevant only when the DW_apb_ssi is configured as a serial-master device. When configured as a serial slave, this bit field has no functionality. Used to enable and disable the busy/ready handshaking interface for the Microwire protocol. When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register.
1	0h RW	**MDD:** Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device.
0	0h RW	**MWMOD:** Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received.

Slave Enable Register - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register enables the individual slave select output lines from the DW_apb_ssi master. Up to 16 slave-select output pins are available on the DW_apb_ssi master. Register bits can be set or cleared when SSI_EN=0. If SSI_EN=1, then register bits can be set (to delay the slave select assertion while TX FIFO is getting filled) but cannot be cleared. 1:0	0h RW	**SER:** Slave Select Enable Flag. Each bit in this register corresponds to a slave select line (ss_x_n) from the DW_apb_ssi master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set.

14.14.4.6 BAUDR — Offset 48106014h

Baud Rate Select - This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the ssi_clk divider value. 14.14.4.61 RX_SAMPLE_DLY — Offset 481060F0h

RX Sample Delay Register - This register is only valid when the DW_apb_ssi is configured with rxd sample delay logic (SSI_HAS_RX_SAMPLE_DELAY==1). When the DW_apb_ssi is not configured with rxd sample delay logic, this register will not exist and writing to its address location will have no effect; reading from its address will return zero. This register control the number of ssi_clk cycles that are delayed (from the default sample time) before the actual sample of the rxd input occurs. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register. Reset Value: 0x0

14.15.1.1 RBR — Offset 48200000h

Receive Buffer Register - Receive Buffer Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Type	Size	Offset	Default
MMIO	32 bit	48200000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

14.15.1.2 IER — Offset 48200004h

Interrupt Enable Register - Interrupt Enable Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**PTIME:** Programmable THRE Interrupt Mode Enable. Writeable only when THRE_MODE_USER == Enabled, always readable. This is used to enable/disable the generation of THRE Interrupt.
6:5	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

5:4	0h RO	**Reserved**
3:0	1h RO/V	**IID:** Interrupt ID (or IID). This indicates the highest priority pending interrupt which can be one of the following types specified in Values. **Note:** an interrupt of type 0111 (busy detect) will never get indicated if UART_16550_COMPATIBLE == YES in coreConsultant. Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt.

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

14.15.1.5 MCR — Offset 48200010h

Modem Control Register - Modem Control Register

Type	Size	Offset	Default
MMIO	32 bit	48200010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.1.6 LSR — Offset 48200014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	48200014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.1.7 MSR — Offset 48200018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default
MMIO	32 bit	48200018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

0	0h WO	**DMASA:** DMA Software Acknowledge. Writes will have no effect when DMA_EXTRA == No. This register is use to perform DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the DW_apb_uart should clear its request. This will cause the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing' and it is not necessary to clear this bit.

14.15.1.15 TCR — Offset 482000ACh

Transceiver Control Register - This register is used to enable or disable RS485 mode and also control the polarity values for Driven enable (de) and Receiver Enable (re) signals. This register is only valid when the DW_apb_uart is configured to have RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address returns zero.

Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.

23:16	00h RW	**DE_DE_ASSERTION_TIME:** Driver Enable de-assertion time. This field controls the amount of time (in terms of number of serial clock periods) between the end of stop bit on the sout to the falling edge of Driver output enable signal.
15:8	0h RO	**Reserved**
7:0	00h RW	**DE_ASSERTION_TIME:** Driver Enable assertion time. This field controls the amount of time (in terms of number of serial clock periods) between the assertion of rising edge of Driver output enable signal to serial transmit enable. Any data in transmit buffer, will start on serial output (sout) after the transmit enable.

14.15.1.19 TAT — Offset 482000BCh

TurnAround Timing Register - The TurnAround Timing Register (TAT) is used to hold the turnaround time between switching of 're' and 'de' signals. This register is only valid when the DW_apb_uart is configured to have the RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address will return zero.

Receive Buffer Register - Receive Buffer Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Type	Size	Offset	Default
MMIO	32 bit	48202000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

6:5	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

5:4	0h RO	**Reserved**
3:0	1h RO/V	**IID:** Interrupt ID (or IID). This indicates the highest priority pending interrupt which can be one of the following types specified in Values. **Note:** an interrupt of type 0111 (busy detect) will never get indicated if UART_16550_COMPATIBLE == YES in coreConsultant. Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt.

14.15.2.4 LCR — Offset 4820200Ch

Line Control Register - Line Control Register

Type	Size	Offset	Default
MMIO	32 bit	4820200Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

Modem Control Register - Modem Control Register

Type	Size	Offset	Default
MMIO	32 bit	48202010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.2.6 LSR — Offset 48202014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	48202014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.2.7 MSR — Offset 48202018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default
MMIO	32 bit	48202018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

Type	Size	Offset	Default
MMIO	32 bit	48202070h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**FAR:** Writes will have no effect when FIFO_ACCESS == No, always readable. This register is use to enable a FIFO access mode for testing, so that the receive FIFO can be written by the master and the transmit FIFO can be read by the master when FIFO's are implemented and enabled. When FIFOs are not implemented or not enabled it allows the RBR to be written by the master and the THR to be read by the master. Note, that when the FIFO access mode is enabled/disabled, the control portion of the receive FIFO and transmit FIFO is reset and the FIFO's are treated as empty.

14.15.2.10 USR — Offset 4820207Ch

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h WO	**DMASA:** DMA Software Acknowledge. Writes will have no effect when DMA_EXTRA == No. This register is use to perform DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the DW_apb_uart should clear its request. This will cause the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing' and it is not necessary to clear this bit.

14.15.2.15 TCR — Offset 482020ACh

Transceiver Control Register - This register is used to enable or disable RS485 mode and also control the polarity values for Driven enable (de) and Receiver Enable (re) signals. This register is only valid when the DW_apb_uart is configured to have RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address returns zero.

Type	Size	Offset	Default

4:3	0h RW	**XFER_MODE:** Transfer Mode. - 0: In this mode, transmit and receive can happen simultaneously. The user can enable DE_EN, RE_EN at any point of time. Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.
2	1h RW	**DE_POL:** Driver Enable Polarity. - 1: DE signal is active high - 0: DE signal is active low
1	1h RW	**RE_POL:** Receiver Enable Polarity. - 1: RE signal is active high - 0: RE signal is active low
0	0h RW	**RS485_EN:** RS485 Transfer Enable. - 0 : In this mode, the transfers are still in the RS232 mode. Receive Buffer Register - Receive Buffer Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Type	Size	Offset	Default
MMIO	32 bit	48204000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

31:8	0h RO	**Reserved**
7:6	0h RO/V	**FIFOSE:** FIFOs Enabled (or FIFOSE). This is used to indicate whether the FIFOs are enabled or disabled.
5:4	0h RO	**Reserved**
3:0	1h RO/V	**IID:** Interrupt ID (or IID). This indicates the highest priority pending interrupt which can be one of the following types specified in Values. **Note:** an interrupt of type 0111 (busy detect) will never get indicated if UART_16550_COMPATIBLE == YES in coreConsultant. Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt.

14.15.3.4 LCR — Offset 4820400Ch

Line Control Register - Line Control Register

Type	Size	Offset	Default
MMIO	32 bit	4820400Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

14.15.3.5 MCR — Offset 48204010h

Modem Control Register - Modem Control Register

Type	Size	Offset	Default
MMIO	32 bit	48204010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.3.6 LSR — Offset 48204014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	48204014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.3.7 MSR — Offset 48204018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default
MMIO	32 bit	48204018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h WO	**DMASA:** DMA Software Acknowledge. Writes will have no effect when DMA_EXTRA == No. This register is use to perform DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the DW_apb_uart should clear its request. This will cause the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing' and it is not necessary to clear this bit.

14.15.3.15 TCR — Offset 482040ACh

Transceiver Control Register - This register is used to enable or disable RS485 mode and also control the polarity values for Driven enable (de) and Receiver Enable (re) signals. This register is only valid when the DW_apb_uart is configured to have RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address returns zero.

4:3	0h RW	**XFER_MODE:** Transfer Mode. - 0: In this mode, transmit and receive can happen simultaneously. The user can enable DE_EN, RE_EN at any point of time. Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.

14.15.4.1 RBR — Offset 48206000h

Receive Buffer Register - Receive Buffer Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Type	Size	Offset	Default
MMIO	32 bit	48206000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.4.6 LSR — Offset 48206014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	48206014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.4.7 MSR — Offset 48206018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default
MMIO	32 bit	48206018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

Writes will have no effect when DMA_EXTRA == No. This register is use to perform DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the DW_apb_uart should clear its request. This will cause the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing' and it is not necessary to clear this bit.

14.15.4.15 TCR — Offset 482060ACh

Transceiver Control Register - This register is used to enable or disable RS485 mode and also control the polarity values for Driven enable (de) and Receiver Enable (re) signals. This register is only valid when the DW_apb_uart is configured to have RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address returns zero.

Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.

14.15.4.19 TAT — Offset 482060BCh

TurnAround Timing Register - The TurnAround Timing Register (TAT) is used to hold the turnaround time between switching of 're' and 'de' signals. This register is only valid when the DW_apb_uart is configured to have the RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address will return zero.

Receive Buffer Register - Receive Buffer Register. This register can be accessed only when the DLAB bit (LCR[7]) is cleared.

Type	Size	Offset	Default
MMIO	32 bit	48208000h	00000000h

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

Line Control Register - Line Control Register

Type	Size	Offset	Default
MMIO	32 bit	4820800Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.5.6 LSR — Offset 48208014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	48208014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.5.7 MSR — Offset 48208018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default
MMIO	32 bit	48208018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8:0	000h RO/V	**RBR:** Receive Buffer Register. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to 0), the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to 1), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost and an over-run error occurs. Note: When UART_9BIT_DATA_EN=0, this field width is 8. When UART_9BIT_DATA_EN=1, this field width is 9.

6:5	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO/V	**ELCOLR:** Interrupt Enable Register: ELCOLR, this bit controls the method for clearing the status in the LSR register. This is applicable only for Overrun Error, Parity Error, Framing Error, and Break Interrupt status bits. 0 = LSR status bits are cleared either on reading Rx FIFO (RBR Read) or On reading LSR register. 1 = LSR status bits are cleared only on reading LSR register. Writeable only when LSR_STATUS_CLEAR == Enabled, always readable.
3	0h RW	**EDSSI:** Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.
2	0h RW	**ELSI:** Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt.
1	0h RW	**ETBEI:** Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.
0	0h RW	**ERBFI:** Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFO's enabled). These are the second highest priority interrupts.

This indicates the highest priority pending interrupt which can be one of the following types specified in Values. **Note:** an interrupt of type 0111 (busy detect) will never get indicated if UART_16550_COMPATIBLE == YES in coreConsultant. Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt.

14.15.6.4 LCR — Offset 4820A00Ch

Line Control Register - Line Control Register

Type	Size	Offset	Default
MMIO	32 bit	4820A00Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7	0h RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH/LPDLL and LPDLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	0h RW	**BC:** Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0h RW	**SP:** Stick Parity. If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	0h RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RW	**PEN:** Parity Enable . If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.
2	0h RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. Note: NOTE: The STOP bit duration implemented by DW_apb_uart may appear longer due to idle time inserted between characters for some configurations and baud clock divisor values in the transmit direction.
1:0	0h RW	**DLS:** Data Length Select (or CLS as used in legacy). If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable and always readable. When DLS_E in LCR_EXT is set to 0, this register is used to select the number of data bits per character that the peripheral will transmit and receive.

14.15.6.5 MCR — Offset 4820A010h

Modem Control Register - Modem Control Register

Type	Size	Offset	Default
MMIO	32 bit	4820A010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access

Bit Range	Default & Access	Field Name (ID): Description
31:7	0h RO	**Reserved**
6	0h RO/V	**SIRE:** SIR Mode Enable . Writeable only when SIR_MODE == Enabled, always readable. **Note:** To enable SIR mode, write the appropriate value to the MCR register before writing to the LCR register.
5	0h RW	**AFCE:** Auto Flow Control Enable . Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**LOOPBACK:** LoopBack Bit . This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0h RW	**OUT2:** OUT2 . This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n. Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0h RW	**OUT1:** OUT1 . This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n. Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	0h RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	0h RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n. The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input.

14.15.6.6 LSR — Offset 4820A014h

Line Status Register - Line Status Register

Type	Size	Offset	Default
MMIO	32 bit	4820A014h	00000060h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:9	0h RO	**Reserved**
8	0h RO/V	**ADDR_RCVD:** Address Received Bit. If 9Bit data mode (LCR_EXT[0]=1) is enabled, this bit is used to indicate the 9th bit of the receive data is set to 1. This bit can also be used to indicate whether the incoming character is address or data. - 1 = Indicates the character is address. - 0 = Indicates the character is data. In the FIFO mode, since the 9th bit is associated with a character received, it is revealed when the character with the 9th bit set to 1 is at the top of the FIFO. Reading the LSR clears the 9BIT. Note: User needs to ensure that interrupt gets cleared (reading LSR register) before the next address byte arrives. If there is a delay in clearing the interrupt, then Software will not be able to distinguish between multiple address related interrupt.
7	0h RO/V	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	1h RO/V	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1h RO/V	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER = Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0h RO/V	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the BI bit (if LSR_STATUS_CLEAR==0). In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Note: If a FIFO is full when a break condition is received, a FIFO overrun occurs. The break condition and all the information associated with it-parity and framing errors-is discarded; any information that a break character was received is lost.

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO/V	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). This happens because the break character implicitly generates a framing error by holding the sin input to logic 0 for longer than the duration of a character. Reading the LSR clears the FE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the FE bit (if LSR_STATUS_CLEAR==0).
2	0h RO/V	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). In this situation, the Parity Error bit is set if parity generation and detection is enabled (LCR[3]=1) and the parity is set to odd (LCR[4]=0). Reading the LSR clears the PE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the PE bit (if LSR_STATUS_CLEAR==0).
1	0h RO/V	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit (if LSR_STATUS_CLEAR==1) Or Reading the LSR or RBR clears the OE bit (if LSR_STATUS_CLEAR==0).
0	0h RO/V	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.

14.15.6.7 MSR — Offset 4820A018h

Modem Status Register - Whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. The bits (bits 0, 1, 3) can be set after a reset-even though their respective modem signals are inactive-because the synchronized version of the modem signals have a reset value of 0 and change to value 1 after reset. To prevent unwanted interrupts due to this change, a read of the MSR register can be performed after reset.

Type	Size	Offset	Default

31:8	0h RO	**Reserved**
7	0h RO/V	**DCD:** Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. That is this bit is the complement dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	0h RO/V	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. That is this bit is the complement ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	0h RO/V	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. That is this bit is the complement dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	0h RO/V	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. That is, this bit is the complement cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. In Loopback Mode (MCR[4] set to one), CTS is the same as MCR[1] (RTS).
3	0h RO/V	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] set to one), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the dcd_n signal remains asserted.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO/V	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] set to one), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	0h RO/V	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] set to one), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the dsr_n signal remains asserted.
0	0h RO/V	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] set to one), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the cts_n signal remains asserted.

0	0h WO	**DMASA:** DMA Software Acknowledge. Writes will have no effect when DMA_EXTRA == No. This register is use to perform DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the DW_apb_uart should clear its request. This will cause the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing' and it is not necessary to clear this bit.

14.15.6.15 TCR — Offset 4820A0ACh

Transceiver Control Register - This register is used to enable or disable RS485 mode and also control the polarity values for Driven enable (de) and Receiver Enable (re) signals. This register is only valid when the DW_apb_uart is configured to have RS485 interface implemented (UART_RS485_INTERFACE_EN = ENABLED). If RS485 interface is not implemented, this register does not exist and reading from this register address returns zero.

Turn around timing as programmed in the TAT register is not applicable in this mode. - 1: In this mode, DE and RE are mutually exclusive. Either DE or RE only one of them is expected to be enabled through programming. Hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. For transmission Hardware will wait if it is in middle of receiving any transfer, before it starts transmitting. - 2: In this mode, DE and RE are mutually exclusive. Once DE_EN/RE_EN is programed - by default 're' will be enabled and DW_apb_uart controller will be ready to receive. If the user programs the TX FIFO with the data then DW_apb_uart, after ensuring no receive is in progress, disable 're' and enable 'de' signal. Once the TX FIFO becomes empty, 're' signal gets enabled and 'de' signal will be disabled. In this mode of operation hardware will consider the Turn Around timings which are programmed in the TAT register while switching from RE to DE or DE to RE. In this mode, 'de' and 're' signals are strictly complementary to each other.

484000B0h	4	TIMER1LOADCOUNT2	00000000h
484000B4h	4	TIMER2LOADCOUNT2	00000000h
484000B8h	4	TIMER3LOADCOUNT2	00000000h
484000BCh	4	TIMER4LOADCOUNT2	00000000h
484000C0h	4	TIMER5LOADCOUNT2	00000000h
484000C4h	4	TIMER6LOADCOUNT2	00000000h
484000C8h	4	TIMER7LOADCOUNT2	00000000h
484000CCh	4	TIMER8LOADCOUNT2	00000000h

14.17.1.1 TIMER1LOADCOUNT — Offset 48400000h

Timer1 Load Count Register - Name: Timer1 Load Count Register Size: 8-32 bits Address Offset: 0x00 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	48400000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER1LOADCOUNT:** Value to be loaded into Timer1. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.2 TIMER1CURRENTVAL — Offset 48400004h

Name: Timer1 Current Value Size: 8-32 bits Address Offset: 4 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400004h	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER1CURRENTVAL:** Current Value of Timer1. This register is supported only when timer_1_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.3 TIMER1CONTROLREG — Offset 48400008h

Timer1 Control Register - Name: Timer1 Control Register Size: 4 bits Address Offset: 8 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer1. You can program each Timer1ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	48400008h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_1_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer1. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer1. 0: free_running mode 1: user_defined count mode NOTE: You must set the Timer1LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer1. 0: disable 1: enable

14.17.1.4 TIMER1EOI — Offset 4840000Ch

Timer1 End-of-Interrupt Register - Name: Timer1 End-of-Interrupt Register Size: 1 bit Address Offset: 12 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	4840000Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER1EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer1.

14.17.1.5 TIMER1INTSTAT — Offset 48400010h

Timer1 Interrupt Status Register - Name: Timer1 Interrupt Status Register Size: 1 bit Address Offset: 16 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER1INTSTAT:** Contains the interrupt status for Timer1.

14.17.1.6 TIMER2LOADCOUNT — Offset 48400014h

Timer2 Load Count Register - Name: Timer2 Load Count Register Size: 8-32 bits Address Offset: 20 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	48400014h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER2LOADCOUNT:** Value to be loaded into Timer2. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.7 TIMER2CURRENTVAL — Offset 48400018h

Timer2 Current Value - Name: Timer2 Current Value Size: 8-32 bits Address Offset: 24 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400018h	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER2CURRENTVAL:** Current Value of Timer2. This register is supported only when timer_2_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.8 TIMER2CONTROLREG — Offset 4840001Ch

Timer2 Control Register - Name: Timer2 Control Register Size: 3 bits Address Offset: 28 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer2. You can program each Timer2ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	4840001Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_2_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer2. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer2. 0: free-running mode 1: user-defined count mode NOTE: You must set the Timer2LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer2. 0: disable 1: enable

14.17.1.9 TIMER2EOI — Offset 48400020h

Timer2 End-of-Interrupt Register - Name: Timer2 End-of-Interrupt Register Size: 1 bit Address Offset: 32 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400020h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER2EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer2.

14.17.1.10 TIMER2INTSTAT — Offset 48400024h

Timer2 Interrupt Status Register - Name: Timer2 Interrupt Status Register Size: 1 bit Address Offset: 36 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400024h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER2INTSTAT:** Contains the interrupt status for Timer2.

14.17.1.11 TIMER3LOADCOUNT — Offset 48400028h

Timer1 Load Count Register - Name: Timer3 Load Count Register Size: 8-32 bits Address Offset: 40 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	48400028h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER3LOADCOUNT:** Value to be loaded into Timer3. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.12 TIMER3CURRENTVAL — Offset 4840002Ch

Timer3 Current Value - Name: Timer3 Current Value Size: 8-32 bits Address Offset: 44 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	4840002Ch	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER3CURRENTVAL:** Current Value of Timer3. This register is supported only when timer_3_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.13 TIMER3CONTROLREG — Offset 48400030h

Timer3 Control Register - Name: Timer3 Control Register Size: 4 bits Address Offset: 48 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer3. You can program each Timer3ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	48400030h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_3_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer3. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer3. 0: free-running mode 1: user-defined count mode NOTE: You must set the Timer3LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer3. 0: disable 1: enable

14.17.1.14 TIMER3EOI — Offset 48400034h

Timer3 End-of-Interrupt Register - Name: Timer3 End-of-Interrupt Register Size: 1 bit Address Offset: 52 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400034h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER3EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer3.

14.17.1.15 TIMER3INTSTAT — Offset 48400038h

Timer3 Interrupt Status Register - Name: Timer3 Interrupt Status Register Size: 1 bit Address Offset: 56 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400038h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER3INTSTAT:** Contains the interrupt status for Timer3.

14.17.1.16 TIMER4LOADCOUNT — Offset 4840003Ch

Timer4 Load Count Register - Name: Timer4 Load Count Register Size: 8-32 bits Address Offset: 60 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	4840003Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER4LOADCOUNT:** Value to be loaded into Timer4. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.17 TIMER4CURRENTVAL — Offset 48400040h

Timer4 Current Value Register - Name: Timer4 Current Value Size: 8-32 bits Address Offset: 64 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400040h	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER4CURRENTVAL:** Current Value of Timer4. This register is supported only when timer_4_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.18 TIMER4CONTROLREG — Offset 48400044h

Timer4 Control Register - Name: Timer4 Control Register Size: 4 bits Address Offset: 68 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer4. You can program each Timer4ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	48400044h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_4_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer4. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer4. 0: free-running mode 1: user-defined count mode NOTE: You must set the Timer4LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer4. 0: disable 1: enable

14.17.1.19 TIMER4EOI — Offset 48400048h

Timer4 End-of-Interrupt Register - Name: Timer4 End-of-Interrupt Register Size: 1 bit Address Offset: 72 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400048h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER4EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer4.

14.17.1.20 TIMER4INTSTAT — Offset 4840004Ch

Timer4 Interrupt Status Register - Name: Timer4 Interrupt Status Register Size: 1 bit Address Offset: 76 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	4840004Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER4INTSTAT:** Contains the interrupt status for Timer4.

14.17.1.21 TIMER5LOADCOUNT — Offset 48400050h

Timer5 Load Count Register - Name: Timer5 Load Count Register Size: 8-32 bits Address Offset: 80 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	48400050h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER5LOADCOUNT:** Value to be loaded into Timer5. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.22 TIMER5CURRENTVAL — Offset 48400054h

Timer5 Current Value - Name: Timer5 Current Value Size: 8-32 bits Address Offset: 84 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400054h	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER5CURRENTVAL:** Current Value of Timer5. This register is supported only when timer_5_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.23 TIMER5CONTROLREG — Offset 48400058h

Timer5 Control Register - Name: Timer5 Control Register Size: 4 bits Address Offset: 88 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer5. You can program each Timer5ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	48400058h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_5_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer5. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer5. 0: free-running mode 1: user-defined count mode NOTE: You must set the Timer5LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer5. 0: disable 1: enable

14.17.1.24 TIMER5EOI — Offset 4840005Ch

Timer5 End-of-Interrupt Register - Name: Timer5 End-of-Interrupt Register Size: 1 bit Address Offset: 92 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	4840005Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER5EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer5.

14.17.1.25 TIMER5INTSTAT — Offset 48400060h

Timer5 Interrupt Status Register - Name: Timer5 Interrupt Status Register Size: 1 bit Address Offset: 96 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400060h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER5INTSTAT:** Contains the interrupt status for Timer5.

14.17.1.26 TIMER6LOADCOUNT — Offset 48400064h

Timer6 Load Count Register - Name: Timer6 Load Count Register Size: 8-32 bits Address Offset: 100 Read/Write Access: Read/Write

Type	Size	Offset	Default
MMIO	32 bit	48400064h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	**TIMER6LOADCOUNT:** Value to be loaded into Timer6. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.

14.17.1.27 TIMER6CURRENTVAL — Offset 48400068h

Timer6 Current Value Register - Name: Timer6 Current Value Size: 8-32 bits Address Offset: 104 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400068h	80000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	80000000h RO/V	**TIMER6CURRENTVAL:** Current Value of Timer6. This register is supported only when timer_6_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.

14.17.1.28 TIMER6CONTROLREG — Offset 4840006Ch

Timer6 Control Register - Name: Timer6 Control Register Size: 4 bits Address Offset: 108 Read/Write Access: Read/Write This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer6. You can program each Timer6ControlReg to enable or disable a specific timer and to control its mode of operation.

Type	Size	Offset	Default
MMIO	32 bit	4840006Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:4	0h RO	**Reserved**
3	0h RW	**TIMER_PWM:** Pulse Width Modulation of timer_6_toggle output. 0: Disabled 1: Enabled This field is only present when TIM_NEWMODE is enabled
2	0h RW	**TIMER_INTERRUPT_MASK:** Timer interrupt mask for Timer6. 0: not masked 1: masked
1	0h RW	**TIMER_MODE:** Timer mode for Timer6. 0: free-running mode 1: user-defined count mode NOTE: You must set the Timer6LoadCount register to all 1s before enabling the timer in free-running mode.
0	0h RW	**TIMER_ENABLE:** Timer enable bit for Timer6. 0: disable 1: enable

14.17.1.29 TIMER6EOI — Offset 48400070h

Timer6 End-of-Interrupt Register - Name: Timer6 End-of-Interrupt Register Size: 1 bit Address Offset: 112 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400070h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:1	0h RO	**Reserved**
0	0h RO/V	**TIMER6EOI:** Reading from this register returns all zeroes (0) and clears the interrupt from Timer6.

14.17.1.30 TIMER6INTSTAT — Offset 48400074h

Timer6 Interrupt Status Register - Name: Timer6 Interrupt Status Register Size: 1 bit Address Offset: 116 Read/Write Access: Read

Type	Size	Offset	Default
MMIO	32 bit	48400074h	00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	0h RO	**Reserved**
7:0	00h RO/V	**TIMERSINTSTAT:** Contains the interrupt status of all timers in the component. If a bit of this register is 0, then the corresponding timer interrupt is not active and the corresponding interrupt could be on either the timer_intr bus or the timer_intr_n bus, depending on the interrupt polarity you have chosen. Similarly, if a bit of this register is 1, then the corresponding interrupt bit has been set in the relevant interrupt bus. In both cases, the status reported is the status after the interrupt mask has been applied. Reading from this register does not clear any active interrupts: 0 = either timer_intr or timer_intr_n is not active after masking 1 = either timer_intr or timer_intr_n is active after masking.

14.17.1.42 TIMERSEOI — Offset 484000A4h

14.18.1.3 QEPCOUNT — Offset 48600008h

QEP Position Counter Register

Type	Size	Offset	Default
MMIO	32 bit	48600008h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO/V	**POS_COUNT:** Position Count Value. It stores the count value currently reached by the position counter. Disabling the peripheral will automatically clear its content.

14.18.1.4 QEPMAX — Offset 4860000Ch

QEP Maximum Position Register

Type	Size	Offset	Default
MMIO	32 bit	4860000Ch	FFFFFFFFh

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	FFFFFFFFh RW/L	**MAX_COUNT:** Maximum Position Count. It defines the operating range for the position counter. It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.1.5 QEPWDT — Offset 48600010h

QEP Watchdog Timer Register

Type	Size	Offset	Default
MMIO	32 bit	48600010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW/L	**TOP:** Watchdog Timer Timeout Period. When the WDT reaches this value, a dedicated interrupt is generated to flag a stall event. It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.1.6 QEPCAPDIV — Offset 48600014h

QEP Capture Divider Register

Type	Size	Offset	Default

14.18.2.1 QEPCON — Offset 48602000h

QEP Control Register. This register controls the QEP operation and provides status flags for the state of the QEP module

Type	Size	Offset	Default
MMIO	32 bit	48602000h	0000001Ch

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:16	0h RO	**Reserved**
15	0h RO/V	**FIFO_EMPTY:** Capture FIFO Empty Status Flag. Set when the FIFO is empty
14:12	0h RW/L	**FIFO_THRE:** Capture FIFO Threshold. It contains the number of valid data entries in the FIFO: NUM_DATA_ENTRIES = FIFO_THRE + 1 It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN
11	0h RW/L	**CAP_MODE:** Capture Block Mode. It selects the PhaseA event which triggers the FIFO to store the current QEPCNTR value 0 = Single edge 1 = Both edges It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

Bit Range	Default & Access	Field Name (ID): Description
10:9	0h RW/L	**INDX_GATING:** Index Gating Select. It selects the state of PhaseA and PhaseB signals at which the index pulse will be gated 00 = PhaseA low and PhaseB low 01 = PhaseA low and PhaseB high 10 = PhaseA high and PhaseB low 11 = PhaseA high and PhaseB high It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.2.2 QEPFLT — Offset 48602004h

QEP Noise Filter Register

Type	Size	Offset	Default
MMIO	32 bit	48602004h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:21	0h RO	**Reserved**
20:0	000000h RW/L	**MAX_COUNT:** Noise Filter Maximum Count. It selects the maximum glitch width to remove in terms of peripheral clock cycles: PCLK_CYCLES = MAX_COUNT + 2 It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.2.3 QEPCOUNT — Offset 48602008h

QEP Position Counter Register

Type	Size	Offset	Default
MMIO	32 bit	48602008h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO/V	**POS_COUNT:** Position Count Value. It stores the count value currently reached by the position counter. Disabling the peripheral will automatically clear its content.

14.18.2.4 QEPMAX — Offset 4860200Ch

QEP Maximum Position Register

Type	Size	Offset	Default
MMIO	32 bit	4860200Ch	FFFFFFFFh

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	FFFFFFFFh RW/L	**MAX_COUNT:** Maximum Position Count. It defines the operating range for the position counter. It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.2.5 QEPWDT — Offset 48602010h

QEP Watchdog Timer Register

Type	Size	Offset	Default
MMIO	32 bit	48602010h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW/L	**TOP:** Watchdog Timer Timeout Period. When the WDT reaches this value, a dedicated interrupt is generated to flag a stall event. It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.2.6 QEPCAPDIV — Offset 48602014h

QEP Capture Divider Register

Type	Size	Offset	Default
MMIO	32 bit	48602014h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:3	0h RO	**Reserved**
2:0	0h RW/L	**CLK_DIV:** Clock Divider Value. It allows the clock to be divided as follows: 000 = clock divided by 1 001 = clock divided by 2 010 = clock divided by 4 011 = clock divided by 8 100 = clock divided by 16 101 = clock divided by 32 110 = clock divided by 64 111 = clock divided by 128 It is writeable by the processor only when the peripheral is disabled. **Locked by:** QEPCON.EN

14.18.2.7 QEPCNTR — Offset 48602018h

QEP Capture Counter Register

Type	Size	Offset	Default
MMIO	32 bit	48602018h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO/V	**CAP_COUNT:** Capture Count Value. It stores the count value currently reached by the free-running capture counter. Disabling the peripheral will automatically clear its content.

14.18.2.8 QEPCAPBUF — Offset 4860201Ch

QEP Capture Data Register

Type	Size	Offset	Default
MMIO	32 bit	4860201Ch	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO/V	**DATA:** This is the register the processor reads from when retrieving bytes from FIFO

14.18.2.9 QEPINT_STAT — Offset 48602020h

QEP Raw Interrupt Status Register. Each bit in this register has a corresponding mask bit in the QEPINT_MASK register. These bits are cleared by writing '1' to the matching interrupt register field.

Type	Size	Offset	Default
MMIO	32 bit	48602020h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:6	0h RO	**Reserved**
5	0h RW/1C/V	**FIFOCRIT/QEP_PH_ERR_INTR:** In Capture mode, Capture Function Event FIFO Critical Interrupt. The number of entries in the Capture FIFO has reached the configured threshold level. In Encoder mode, this bit is set when phase error has occurred on the QEP inputs.
4	0h RW/1C/V	**FIFOENTRY:** Capture Function Event FIFO Entry Interrupt. An entry has been added to the 'Capture' FIFO.
3	0h RW/1C/V	**QEPDIR:** QEP Function Change Of Direction Detected Interrupt. The Quadrature Decoder has detected that the attached motor (or user dial device) has changed direction.
2	0h RW/1C/V	**QEPRST_UP:** QEPCOUNT Reset detect with forward count direction Interrupt; The QEPCOUNT can be reset by one of 2 configurable methods: Index Input detect event or comparator match event
1	0h RW/1C/V	**QEPRST_DOWN:** QEPCOUNT Reset detect with reverse count direction Interrupt; The QEPCOUNT can be reset by one of 2 configurable methods: Index Input detect event or comparator match event
0	0h RW/1C/V	**WDT:** Watchdog Timeout Interrupt. The Watchdog Timer value has reached the watchdog comparator value.

14.18.2.10 QEPINT_MASK — Offset 48602024h

QEP Interrupt Mask Register

Type	Size	Offset	Default
MMIO	32 bit	48602024h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:6	0h RO	**Reserved**
5	0h RW	**FIFOCRIT:** This bit masks the FIFOCRIT interrupt bit from the QEPINT_STAT register
4	0h RW	**FIFOENTRY:** This bit masks the FIFOENTRY interrupt bit from the QEPINT_STAT register
3	0h RW	**QEPDIR:** This bit masks the QEPDIR interrupt bit from the QEPINT_STAT register
2	0h RW	**QEPRST_UP:** This bit masks the QEPRST_UP interrupt bit from the QEPINT_STAT register
1	0h RW	**QEPRST_DOWN:** This bit masks the QEPRST_DOWN interrupt bit from the QEPINT_STAT register
0	0h RW	**WDT:** This bit masks the WDT interrupt bit from the QEPINT_STAT register

14.19.1.35 D0i3 Control (D0I3C) — Offset 50101410h

This register is will be used for D0i3 SW flow. This will be mapped to a different MMIO address from the other IPC registers. (MMIO and OCP address value are yet to be done) The description below also includes the type of access expected for the ISH FW for each configuration bit: 1. The Restore Required (RR) bit (bit [3]) should be RW for the ISH FW which can determine when to set and/or clear these bits depending on when the ISH FW determines whether restore is required although for ISH restore is never required since the power is never lost. 2. The D0i3 (i3) bit (bit [2]) should be RO for ISH FW as it needs to be written only by host SW. The ISH FW can determine to go to a low power state based on this bit. 3. The Interrupt Required (IR) bit (bit [1]) can be RO register for ISH FW and ISH FW can send an interrupt to Host by writing to the ish2host IPC doorbell register when this bit is set by SW. 4. The Command in Progress (CIP) register bit (bit [0]) is HW set and need to be cleared by ISH FW (Write 1 to clear). The CIP register bit will be tied to a RTE entry in the IOAPIC as an interrupt source. Hence ISH FW will get an interrupt when the In addition to the registers, the IOSF2OCP Bridge should be parameterized for the following: 1. The device idle capability parameter (ENABLE_PCI_IDLE_CAP) need to be connected to a soft strap for ISH with a value of 1. 2. The STRAP for the MMIO address (strap_d0i3_offset) of D0i3 register (IPC offset address: h6D0) and the d0i3 valid (strap_d0i3_valid) bit needs should be appropriately tied. 3. The PCE register is made RO register by setting the appropriate parameter (Bridge top level strap: set_device_pg_config_type[5:0] is set to all 0s). This registers reset and clock domain will be in the OCP domain.

Bit Range	Default & Access	Field Name (ID): Description
31:5	0h RO	**Reserved**
4	0h RO	**Interrupt Request Capable (IRC):** Set to 1 by HW if it is capable of generating an interrupt on command completion, else 0. For ISH this bit will be tied to 0.
3	1h RW/1C	**Restore Required (RR):** When set (by HW), SW must restore state to the IP. The state may have been lost due to a reset or full power lost. SW clears the bit by writing a 1. This bit will be set on initial power up.
2	0h RW	**D0I3:** SW sets this bit to 1 to move the IP into the D0i3 state. Writing this bit to 0 will return the IP to the fully active D0 state (D0i0).
1	0h RW	**Interrupt Required (IR):** SW sets this bit to 1 to ask for an interrupt to be generated on completion of the command. SW must clear or set this on each write to this register.
0	0h RW/1C	**Command In Progress (CIP):** HW sets this bit on a 1->0 or 0->1 transition of bit [2]. While set, the other bits in this register are not valid and it is illegal for SW to write to any bit in this register. When clear all the other bits in the register are valid and SW may write to any bit.

14.19.2.35 D0i3 Control (D0I3C) — Offset 50105410h

This register is will be used for D0i3 SW flow. This will be mapped to a different MMIO address from the other IPC registers. (MMIO and OCP address value are yet to be done) The description below also includes the type of access expected for the ISH FW for each configuration bit: 1. The Restore Required (RR) bit (bit [3]) should be RW for the ISH FW which can determine when to set and/or clear these bits depending on when the ISH FW determines whether restore is required although for ISH restore is never required since the power is never lost. 2. The D0i3 (i3) bit (bit [2]) should be RO for ISH FW as it needs to be written only by host SW. The ISH FW can determine to go to a low power state based on this bit. 3. The Interrupt Required (IR) bit (bit [1]) can be RO register for ISH FW and ISH FW can send an interrupt to Host by writing to the ish2host IPC doorbell register when this bit is set by SW. 4. The Command in Progress (CIP) register bit (bit [0]) is HW set and need to be cleared by ISH FW (Write 1 to clear). The CIP register bit will be tied to a RTE entry in the IOAPIC as an interrupt source. Hence ISH FW will get an interrupt when the In addition to the registers, the IOSF2OCP Bridge should be parameterized for the following: 1. The device idle capability parameter (ENABLE_PCI_IDLE_CAP) need to be connected to a soft strap for ISH with a value of 1. 2. The STRAP for the MMIO address (strap_d0i3_offset) of D0i3 register (IPC offset address: h6D0) and the d0i3 valid (strap_d0i3_valid) bit needs should be appropriately tied. 3. The PCE register is made RO register by setting the appropriate parameter (Bridge top level strap: set_device_pg_config_type[5:0] is set to all 0s). This registers reset and clock domain will be in the OCP domain.

31:5	0h RO	**Reserved**
4	0h RO	**Interrupt Request Capable (IRC):** Set to 1 by HW if it is capable of generating an interrupt on command completion, else 0. For ISH this bit will be tied to 0.
3	1h RW/1C	**Restore Required (RR):** When set (by HW), SW must restore state to the IP. The state may have been lost due to a reset or full power lost. SW clears the bit by writing a 1. This bit will be set on initial power up.
2	0h RW	**D0I3:** SW sets this bit to 1 to move the IP into the D0i3 state. Writing this bit to 0 will return the IP to the fully active D0 state (D0i0).
1	0h RW	**Interrupt Required (IR):** SW sets this bit to 1 to ask for an interrupt to be generated on completion of the command. SW must clear or set this on each write to this register.
0	0h RW/1C	**Command In Progress (CIP):** HW sets this bit on a 1->0 or 0->1 transition of bit [2]. While set, the other bits in this register are not valid and it is illegal for SW to write to any bit in this register. When clear all the other bits in the register are valid and SW may write to any bit.

14.19.3.10 DMA CH1 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH1) — Offset 50109104h

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.11 DMA CH2 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH2) — Offset 50109108h

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.12 DMA CH3 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH3) — Offset 5010910Ch

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.13 DMA CH4 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH4) — Offset 50109110h

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.14 DMA CH5 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH5) — Offset 50109114h

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.15 DMA CH6 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH6) — Offset 50109118h

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.16 DMA CH7 Read Address Fillin (IOSF_ADDR_FILLIN_DMA_CH7) — Offset 5010911Ch

This register defines the upper MSB bits of maddress port to drive on the IOSF maddr for reads.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.17 DMA CH0 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH0) — Offset 50109200h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.18 DMA CH1 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH1) — Offset 50109204h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.19 DMA CH2 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH2) — Offset 50109208h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.20 DMA CH3 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH3) — Offset 5010920Ch

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.21 DMA CH4 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH4) — Offset 50109210h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.22 DMA CH5 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH5) — Offset 50109214h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.23 DMA CH6 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH6) — Offset 50109218h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.24 DMA CH7 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH7) — Offset 5010921Ch

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50109100h.

14.19.3.25 DMA Crossbar HW Handshake Interface Select Channel 0 (DMA_XBAR_SEL0) — Offset 50109300h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 0.

14.19.3.26 DMA Crossbar HW Handshake Interface Select Channel 1 (DMA_XBAR_SEL1) — Offset 50109304h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 1.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.27 DMA Crossbar HW Handshake Interface Select Channel 2 (DMA_XBAR_SEL2) — Offset 50109308h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 2.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.28 DMA Crossbar HW Handshake Interface Select Channel 3 (DMA_XBAR_SEL3) — Offset 5010930Ch

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 3.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.29 DMA Crossbar HW Handshake Interface Select Channel 4 (DMA_XBAR_SEL4) — Offset 50109310h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 4.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.30 DMA Crossbar HW Handshake Interface Select Channel 5 (DMA_XBAR_SEL5) — Offset 50109314h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 5.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.31 DMA Crossbar HW Handshake Interface Select Channel 6 (DMA_XBAR_SEL6) — Offset 50109318h

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 6.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.32 DMA Crossbar HW Handshake Interface Select Channel 7 (DMA_XBAR_SEL7) — Offset 5010931Ch

This register is used to program the DMA Hardware Handshake crossbar to route the peripheral lines to DMA channel 7.

Note: Bit definitions are the same as DMA_XBAR_SEL0, offset 50109300h.

14.19.3.33 DMA Channel Id Config (DMA_REGACCESS_CHID_CFG) — Offset 50109400h

This reg is used to program the Mreqinfo fo the DMA channel to be programmed next by FW.

Bit 1-8 of this register indicate BAR remap error for the peripherals I2C0-7, Bits 9-14 indicate for UART0-5, bits 15-18 indicate for SPI0-3, Bits 19-20 inidicate for I2S0-1 resp. and Bit 21 is reserved.
0	0h RW/1C	**Sresp Error Status Bit (ECC_ERR_SRESP):** This Error status bit is set on the Rd/Wr Sresp error on the DMA Rd/Wr ports and cleared when '1' is written to it.

14.19.3.35 D0i3 Control (D0I3C) — Offset 50109410h

This register is will be used for D0i3 SW flow. This will be mapped to a different MMIO address from the other IPC registers. (MMIO and OCP address value are yet to be done) The description below also includes the type of access expected for the ISH FW for each configuration bit: 1. The Restore Required (RR) bit (bit [3]) should be RW for the ISH FW which can determine when to set and/or clear these bits depending on when the ISH FW determines whether restore is required although for ISH restore is never required since the power is never lost. 2. The D0i3 (i3) bit (bit [2]) should be RO for ISH FW as it needs to be written only by host SW. The ISH FW can determine to go to a low power state based on this bit. 3. The Interrupt Required (IR) bit (bit [1]) can be RO register for ISH FW and ISH FW can send an interrupt to Host by writing to the ish2host IPC doorbell register when this bit is set by SW. 4. The Command in Progress (CIP) register bit (bit [0]) is HW set and need to be cleared by ISH FW (Write 1 to clear). The CIP register bit will be tied to a RTE entry in the IOAPIC as an interrupt source. Hence ISH FW will get an interrupt when the In addition to the registers, the IOSF2OCP Bridge should be parameterized for the following: 1. The device idle capability parameter (ENABLE_PCI_IDLE_CAP) need to be connected to a soft strap for ISH with a value of 1. 2. The STRAP for the MMIO address (strap_d0i3_offset) of D0i3 register (IPC offset address: h6D0) and the d0i3 valid (strap_d0i3_valid) bit needs should be appropriately tied. 3. The PCE register is made RO register by setting the appropriate parameter (Bridge top level strap: set_device_pg_config_type[5:0] is set to all 0s). This registers reset and clock domain will be in the OCP domain.

Type	Size	Offset	Default
MMIO	32 bit	50109410h	00000008h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:5	0h RO	**Reserved**
4	0h RO	**Interrupt Request Capable (IRC):** Set to 1 by HW if it is capable of generating an interrupt on command completion, else 0. For ISH this bit will be tied to 0.
3	1h RW/1C	**Restore Required (RR):** When set (by HW), SW must restore state to the IP. The state may have been lost due to a reset or full power lost. SW clears the bit by writing a 1. This bit will be set on initial power up.
2	0h RW	**D0I3:** SW sets this bit to 1 to move the IP into the D0i3 state. Writing this bit to 0 will return the IP to the fully active D0 state (D0i0).
1	0h RW	**Interrupt Required (IR):** SW sets this bit to 1 to ask for an interrupt to be generated on completion of the command. SW must clear or set this on each write to this register.
0	0h RW/1C	**Command In Progress (CIP):** HW sets this bit on a 1->0 or 0->1 transition of bit [2]. While set, the other bits in this register are not valid and it is illegal for SW to write to any bit in this register. When clear all the other bits in the register are valid and SW may write to any bit.

14.19.3.36 Clock Gating And Soft Reset (CGSR) — Offset 50109414h

This register is used to Clock gate or soft reset an IP by Host/Remote Host.

Bit Range	Default & Access	Field Name (ID): Description
31	0h RW	**ARP Offload Enable (ARPEN):** When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus. This bit is available only when the Enable IPv4 ARP Offload is selected. 0x0 (DISABLE): ARP Offload is disabled. 0x1 (ENABLE): ARP Offload is enabled.
30:28	0h RW	**Source Address Insertion or Replacement Control (SARC):** This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 0x0 (SA_CTRL_IN): mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 0x2 (MAC0_INS_SA): Contents of MAC Addr-0 inserted in SA field. 0x3 (MAC0_REP_SA): Contents of MAC Addr-0 replaces SA field. 0x6 (MAC1_INS_SA): Contents of MAC Addr-1 inserted in SA field. 0x7 (MAC1_REP_SA): Contents of MAC Addr-1 replaces SA field..
27	0h RW	**Checksum Offload (IPC):** When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0x0 (DISABLE): IP header/payload checksum checking is disabled. 0x1 (ENABLE): IP header/payload checksum checking is enabled.

Bit Range	Default & Access	Field Name (ID): Description
26:24	0h RW	**Inter-Packet Gap (IPG):** These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 0x0 (IPG96): 96 bit times IPG. 0x1 (IPG88): 88 bit times IPG. 0x2 (IPG80): 80 bit times IPG. 0x3 (IPG72): 72 bit times IPG. 0x4 (IPG64): 64 bit times IPG. 0x5 (IPG56): 56 bit times IPG. 0x6 (IPG48): 48 bit times IPG. 0x7 (IPG40): 40 bit times IPG.
23	0h RW	**Giant Packet Size Limit Control Enable (GPSLCE):** When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0x0 (DISABLE): Giant Packet Size Limit Control is disabled. 0x1 (ENABLE): Giant Packet Size Limit Control is enabled.
22	0h RW	**IEEE 802.3as Support for 2K Packets (S2KP):** When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0x0 (DISABLE): Support upto 2K packet is disabled. 0x1 (ENABLE): Support upto 2K packet is Enabled.
21	0h RW	**CRC stripping for Type packets (CST):** When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. 0x0 (DISABLE): CRC stripping for Type packets is disabled. 0x1 (ENABLE): CRC stripping for Type packets is enabled.

Bit Range	Default & Access	Field Name (ID): Description
20	0h RW	**Automatic Pad or CRC Stripping (ACS):** When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. 0x0 (DISABLE): Automatic Pad or CRC Stripping is disabled. 0x1 (ENABLE): Automatic Pad or CRC Stripping is enabled..
19	0h RW	**Watchdog Disable (WD):** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0x0 (ENABLE): Watchdog is enabled. 0x1 (DISABLE): Watchdog is disabled.
18	0h RW	**Packet Burst Enable (BE)**: When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0x0 (DISABLE): Packet Burst is disabled. 0x1 (ENABLE): Packet Burst is enabled..
17	0h RW	**Jabber Disable (JD):** When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0x0 (ENABLE): Jabber is enabled. 0x1 (DISABLE): Jabber is disabled.
16	0h RW	**Jumbo Packet Enable (JE):** When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0x0 (DISABLE): Jumbo packet is disabled. 0x1 (ENABLE): Jumbo packet is enabled.
15	0h RW	**Port Select (PS):** This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read/write (R/W). 0x0 (M_1000_2500M): For 1000 or 2500 Mbps operations. 0x1 (M_10_100M): For 10 or 100 Mbps operations.
14	0h RW	**FES:** This bit selects the speed mode. 0x0 (M_10_1000M): 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0. 0x1 (M_100_2500M): 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0.
13	0h RW	**Duplex Mode (DM):** When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the fullduplex-only configurations. 0x0 (HDUPLX): Half-duplex mode. 0x1 (FDUPLX): Full-duplex mode.

Bit Range	Default & Access	Field Name (ID): Description
12	0h RW	**Loopback Mode (LM):** When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0x0 (DISABLE): Loopback is disabled. 0x1 (ENABLE): Loopback is enabled.
11	0h RW	**Enable Carrier Sense Before Transmission in Full-Duplex Mode (ECRSFD):** When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0x0 (DISABLE): ECRSFD is disabled. 0x1 (ENABLE): ECRSFD is enabled.
10	0h RW	**Disable Receive Own (DO):** When this bit is set, the MAC disables the reception of packets when the GMII signal TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0x0 (ENABLE): Enable Receive Own. 0x1 (DISABLE): Disable Receive Own.
9	0h RW	**Disable Carrier Sense During Transmission (DCRS)**: When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0x0 (ENABLE): Enable Carrier Sense During Transmission. 0x1 (DISABLE): Disable Carrier Sense During Transmission.
8	0h RW	**Disable Retry (DR):** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0x0 (ENABLE): Enable Retry. 0x1 (DISABLE): Disable Retry.
7	0h RO	**Reserved**
6:5	0h RW	**Back-Off Limit (BL):** The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 0x0 (MIN_N_10): k = min(n,10). 0x1 (MIN_N_8): k = min(n,8). 0x2 (MIN_N_4): k = min(n,4). 0x3 (MIN_N_1): k = min(n,1).

Bit Range	Default & Access	Field Name (ID): Description
4	0h RW	**Deferral Check (DC):** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0x0 (DISABLE): Deferral check function is disabled. 0x1 (ENABLE): Deferral check function is enabled.
3:2	0h RW	**Preamble Length for Transmit packets (PRELEN):** These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 0x0 (M_7BYTES): 7 bytes of preamble. 0x1 (M_5BYTES): 5 bytes of preamble. 0x2 (M_3BYTES): 3 bytes of preamble. 0x3 (RESERVED): Reserved.
1	0h RW	**Transmitter Enable (TE):** When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0x0 (DISABLE): Transmitter is disabled. 0x1 (ENABLE): Transmitter is enabled.
0	0h RW	**Receiver Enable (RE):** When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

14.20.1.3 MAC_PACKET_FILTER — Offset 50200008h

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

14.20.1.5 MAC_HASH_TABLE_REG0 — Offset 50200010h

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the DA
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the

corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

14.20.1.6 MAC_HASH_TABLE_REG1 — Offset 50200014h

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the DA.
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] of the Hash Table Register X registers are written. 14.20.1.9 MAC_VLAN_HASH_TABLE — Offset 50200058h

When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated hash value are used to index the contents of the VLAN Hash table. For example, hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the VLAN tag or ID.
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2. If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] of this register are written.
- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

14.20.1.12 MAC_Q0_TX_FLOW_CTRL — Offset 50200070h

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register. When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. 31:9	0h RO	**Reserved**
8	0h RO	**Receive Watchdog Timeout (RWT):** This bit is set when a packet with length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No receive watchdog timeout. 0x1 (ACTIVE): Receive watchdog timed out.
7:6	0h RO	**Reserved**
5	0h RO	**Excessive Collisions (EXCOL):** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No collision. 0x1 (ACTIVE): Excessive collision is sensed.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO	**Late Collision (LCOL):** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No collision. 0x1 (ACTIVE): Late collision is sensed.
3	0h RO	**Excessive Deferral (EXDEF):** When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No Excessive deferral. 0x1 (ACTIVE): Excessive deferral.
2	0h RO	**Loss of Carrier (LCARR):** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): Carrier is present. 0x1 (ACTIVE): Loss of carrier.
1	0h RO	**No Carrier (NCARR):** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): Carrier is present. 0x1 (ACTIVE): No carrier.
0	0h RO	**Transmit Jabber Timeout (TJT):** This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No Transmit Jabber Timeout. 0x1 (ACTIVE): Transmit Jabber Timeout occurred.

31	0h RW	**Remote Wake-Up Packet Filter Register Pointer Reset (RWKFILTRST):** When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Remote Wake-Up Packet Filter Register Pointer is not Reset. 0x1 (ENABLE): Remote Wake-Up Packet Filter Register Pointer is Reset.
30:29	0h RO	**Reserved**
28:24	00h RO	**Remote Wake-up FIFO Pointer (RWKPTR):** This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23:11	0h RO	**Reserved**
10	0h RW	**Remote Wake-up Packet Forwarding Enable (RWKPFE):** When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Remote Wake-up Packet Forwarding is disabled. 0x1 (ENABLE): Remote Wake-up Packet Forwarding is enabled.
9	0h RW	**Global Unicast (GLBLUCAST):** When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0x0 (DISABLE): Global unicast is disabled. 0x1 (ENABLE): Global unicast is enabled.
8:7	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
6	0h RO	**Remote Wake-Up Packet Received (RWKPRCVD):** When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): Remote wake-up packet is received. 0x1 (ACTIVE): Remote wake-up packet is received.
5	0h RO	**Magic Packet Received (MGKPRCVD):** When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0x0 (INACTIVE): No Magic packet is received. 0x1 (ACTIVE): Magic packet is received.
4:3	0h RO	**Reserved**
2	0h RW	**Remote Wake-Up Packet Enable (RWKPKTEN):** When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0x0 (DISABLE): Remote wake-up packet is disabled. 0x1 (ENABLE): Remote wake-up packet is enabled.
1	0h RW	**Magic Packet Enable (MGKPKTEN):** When this bit is set, a power management event is generated when the MAC receives a magic packet. 0x0 (DISABLE): Magic Packet is disabled. 0x1 (ENABLE): Magic Packet is enabled.
0	0h RW	**Power Down (PWRDWN):** When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Power down is disabled. 0x1 (ENABLE): Power down is enabled.

14.20.1.32 MAC_RWK_PACKET_FILTER — Offset 502000C4h

The TSN-GbE implements a filter lookup table programmed through the MAC_RWK_Packet_Filter register in which CRC, offset, and byte mask of the pattern embedded in the remote wakeup packet, and the filter-operation commands are programmed.

14.20.1.33 MAC_LPI_CONTROL_STATUS — Offset 502000D0h

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Type	Size	Offset	Default
MMIO	32 bit	502000D0h	00000000h

Register Level Access:

Bit Range	Default & Access	Field Name (ID): Description
31:22	0h RO	**Reserved**
21	0h RW	**LPI Tx Clock Stop Enable (LPITCSE):** When this bit is set, the MAC indicates that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not indicate that the Tx clock to MAC can be stopped after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0x0 (DISABLE): LPI Tx Clock Stop is disabled. 0x1 (ENABLE): LPI Tx Clock Stop is enabled.
20	0h RW	**LPI Timer Enable (LPIATE):** This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0x0 (DISABLE): LPI Timer is disabled. 0x1 (ENABLE): LPI Timer is enabled.

Bit Range	Default & Access	Field Name (ID): Description
19	0h RW	**LPI Tx Automate (LPITXA):** This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0x0 (DISABLE): LPI Tx Automate is disabled. 0x1 (ENABLE): LPI Tx Automate is enabled.
18	0h RW	**PHY Link Status Enable (PLSEN):** This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_Control_Status register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_Control_Status register and takes only the PLS bit. 0x0 (DISABLE): PHY Link Status is disabled. 0x1 (ENABLE): PHY Link Status is enabled.
17	0h RW	**PHY Link Status (PLS):** This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0x0 (DISABLE): link is down. 0x1 (ENABLE): link is okay (UP).
16	0h RW	**LPI Enable (LPIEN):** When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0x0 (DISABLE): LPI state is disabled. 0x1 (ENABLE): LPI state is enabled.
15:10	0h RO	**Reserved**
9	0h RO	**Receive LPI State (RLPIST):** When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. 0x0 (INACTIVE): Receive LPI state not detected. 0x1 (ACTIVE): Receive LPI state detected.
8	0h RO	**Transmit LPI State (TLPIST):** When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. 0x0 (INACTIVE): Transmit LPI state not detected. 0x1 (ACTIVE): Transmit LPI state detected.
7:4	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
3	0h RO	**Receive LPI Exit (RLPIEX):** When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0x0 (INACTIVE): Receive LPI exit not detected. 0x1 (ACTIVE): Receive LPI exit detected.
2	0h RO	**Receive LPI Entry (RLPIEN):** When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0x0 (INACTIVE): Receive LPI entry not detected. 0x1 (ACTIVE): Receive LPI entry detected.
1	0h RO	**Transmit LPI Exit (TLPIEX):** When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0x0 (INACTIVE): Transmit LPI exit not detected. 0x1 (ACTIVE): Transmit LPI exit detected.
0	0h RO	**Transmit LPI Entry (TLPIEN):** When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0x0 (INACTIVE): Transmit LPI entry not detected. 0x1 (ACTIVE): Transmit LPI entry detected.

14.20.1.34 MAC_LPI_TIMERS_CONTROL — Offset 502000D4h

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

26	0h RW	**Back to Back transactions (BTB):** When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0x0 (DISABLE): Back to Back transactions disabled. 0x1 (ENABLE): Back to Back transactions enabled.

The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11:8	0h RW	**CSR Clock Range (CR):** The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12 - 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18

0	0h RW	**GMII Busy (GB):** The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDl field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): GMII Busy is disabled. 0x1 (ENABLE): GMII Busy is enabled.

14.20.1.58 MAC_ADDRESS0_HIGH — Offset 50200300h

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if

0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

29:24	00h RW	**Mask Byte Control (MBC):** These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: - Bit 29: MAC_Address${i}_High[15:8] - Bit 28: MAC_Address${i}_High[7:0] - Bit 27: MAC_Address${i}_Low[31:24] - .. - Bit 24: MAC_Address${i}_Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23:16	00h RW	**DMA Channel Select (DCS):** If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15:0	FFFFh RW	**MAC Address1 [47:32] (ADDRHI):** This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.

14.20.1.61 MAC_ADDRESS1_LOW — Offset 5020030Ch

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Type	Size	Offset	Default
MMIO	32 bit	5020030Ch	FFFFFFFFh

Register Level Access:

BIOS Access	SMM Access	OS Access

Bit Range	Default & Access	Field Name (ID): Description
31:0	FFFFFFFFh RW	**MAC Address1 [31:0] (ADDRLO):** This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

14.20.1.62 MAC_ADDRESS2_HIGH — Offset 50200310h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Note: Bit definitions are the same as MAC_ADDRESS1_HIGH, offset 50200308h.

14.20.1.63 MAC_ADDRESS2_LOW — Offset 50200314h

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.64 MAC_ADDRESS3_HIGH — Offset 50200318h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Note: Bit definitions are the same as MAC_ADDRESS1_HIGH, offset 50200308h.

14.20.1.65 MAC_ADDRESS3_LOW — Offset 5020031Ch

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.66 MAC_ADDRESS4_HIGH — Offset 50200320h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Note: Bit definitions are the same as MAC_ADDRESS1_HIGH, offset 50200308h.

14.20.1.67 MAC_ADDRESS4_LOW — Offset 50200324h

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.68 MAC_ADDRESS5_HIGH — Offset 50200328h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Note: Bit definitions are the same as MAC_ADDRESS1_HIGH, offset 50200308h.

14.20.1.69 MAC_ADDRESS5_LOW — Offset 5020032Ch

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.70 MAC_ADDRESS6_HIGH — Offset 50200330h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Note: Bit definitions are the same as MAC_ADDRESS1_HIGH, offset 50200308h.

14.20.1.71 MAC_ADDRESS6_LOW — Offset 50200334h

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.72 MAC_ADDRESS7_HIGH — Offset 50200338h

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS1_LOW, offset 5020030Ch.

14.20.1.122MAC_ADDRESS32_HIGH — Offset 50200400h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Type	Size	Offset	Default
MMIO	32 bit	50200400h	0000FFFFh

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31	0h RW	**Address Enable (AE):** When this bit is set, the Address filter module uses the 33rd MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0x0 (DISABLE): Address is ignored. 0x1 (ENABLE): Address is enabled.
30:19	0h RO	**Reserved**
18:16	0h RW	**DMA Channel Select (DCS):** This field contains the DMA Channel number to which an Rx packet whose DA matches the MAC Address32 content is routed.
15:0	FFFFh RW	**MAC Address32 [47:32] (ADDRHI):** This field contains the upper 16 bits (47:32) of the 33rd 6-byte MAC address.

14.20.1.123MAC_ADDRESS32_LOW — Offset 50200404h

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Type	Size	Offset	Default
MMIO	32 bit	50200404h	FFFFFFFFh

Register Level Access:

Bit Range	Default & Access	Field Name (ID): Description
31:0	FFFFFFFFh RW	**MAC Address32 [31:0] (ADDRLO):** This field contains the lower 32 bits of the 33rd 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

14.20.1.124MAC_ADDRESS33_HIGH — Offset 50200408h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.125MAC_ADDRESS33_LOW — Offset 5020040Ch

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.126MAC_ADDRESS34_HIGH — Offset 50200410h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.127MAC_ADDRESS34_LOW — Offset 50200414h

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.128MAC_ADDRESS35_HIGH — Offset 50200418h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.129MAC_ADDRESS35_LOW — Offset 5020041Ch

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.130MAC_ADDRESS36_HIGH — Offset 50200420h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.131MAC_ADDRESS36_LOW — Offset 50200424h

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.132MAC_ADDRESS37_HIGH — Offset 50200428h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.133MAC_ADDRESS37_LOW — Offset 5020042Ch

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.134MAC_ADDRESS38_HIGH — Offset 50200430h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. 14.20.1.180MAC_ADDRESS61_HIGH — Offset 502004E8h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.181MAC_ADDRESS61_LOW — Offset 502004ECh

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.182MAC_ADDRESS62_HIGH — Offset 502004F0h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

14.20.1.183MAC_ADDRESS62_LOW — Offset 502004F4h

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.184MAC_ADDRESS63_HIGH — Offset 502004F8h

The MAC Address32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Note: Bit definitions are the same as MAC_ADDRESS32_HIGH, offset 50200400h.

14.20.1.185MAC_ADDRESS63_LOW — Offset 502004FCh

The MAC Address32 Low register holds the lower 16 bits of the 33rd 6-byte MAC address of the station.

Note: Bit definitions are the same as MAC_ADDRESS32_LOW, offset 50200404h.

14.20.1.186MMC_CONTROL — Offset 50200700h

This register establishes the operating mode of MAC Management Counters.

8	0h RW	**Update MMC Counters for Dropped Broadcast Packets (UCDBC):** Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0x0 (DISABLE): Update MMC Counters for Dropped Broadcast Packets is disabled. 0x1 (ENABLE): Update MMC Counters for Dropped Broadcast Packets is enabled.
7:6	0h RO	**Reserved**
5	0h RW	**Full-Half Preset (CNTPRSTLVL):** When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0x0 (DISABLE): Full-Half Preset is disabled. 0x1 (ENABLE): Full-Half Preset is enabled.
4	0h RW	**Counters Preset (CNTPRST):** When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0x0 (DISABLE): Counters Preset is disabled. 0x1 (ENABLE): Counters Preset is enabled.
3	0h RW	**MMC Counter Freeze (CNTFREEZ):** When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0x0 (DISABLE): MMC Counter Freeze is disabled. 0x1 (ENABLE): MMC Counter Freeze is enabled.

2	0h RW	**Reset on Read (RSTONRD):** When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0x0 (DISABLE): Reset on Read is disabled. 0x1 (ENABLE): Reset on Read is enabled.
1	0h RW	**Counter Stop Rollover (CNTSTOPRO):** When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0x0 (DISABLE): Counter Stop Rollover is disabled. 0x1 (ENABLE): Counter Stop Rollover is enabled.
0	0h RW	**Counters Reset (CNTRST):** When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0x0 (DISABLE): Counters are not reset. 0x1 (ENABLE): All counters are reset.

14.20.1.187MMC_RX_INTERRUPT — Offset 50200704h

This register maintains the interrupts generated from all Receive statistics counters. The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).

- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit. Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

14.20.1.248MMC_IPC_RX_INTERRUPT — Offset 50200808h

This register maintains the interrupt that the receive IPC statistic counters generate. The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

14.20.1.277MMC_FPE_TX_INTERRUPT — Offset 502008A0h

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

14.20.1.281MMC_FPE_RX_INTERRUPT — Offset 502008C0h

This register maintains the interrupts generated from all FPE related Receive statistics counters. The MMC FPE Receive Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

The MAC_Layer4_Address(#i), MAC_L3_L4_Control(#i), MAC_Layer3_Addr0_Reg(#i), MAC_Layer3_Addr1_Reg(#i), MAC_Layer3_Addr2_Reg(#i) and MAC_Layer3_Addr3_Reg(#i) registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core. You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

14.20.1.308MAC_TX_TIMESTAMP_STATUS_NANOSECONDS — Offset 50200B30h

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte (bits[31:24]) of MAC_Tx_Timestamp_Status_Nanoseconds is read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [15] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

3:0	0h RW	**PPS Output Frequency Control (PPSCTRL_PPSCMD):** This field controls the frequency of the PPS0 output signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - .. - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output signal has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: - When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms - When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) - When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates single pulse rising at the start point defined in MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds register and of a duration defined in the PPS0 Width Register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111-1111: Reserved or Presentation Time Control If MCGREN0 is set then these bits are treated as Presentation time control bits. The following list describes the values of PPSCMD0: - 0000: MCGR operation is not carried out. If set to this value in the mid of clock recovery or generation, all the processing inputs are flushed - 0001: Capture the Presentation time at the rising edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0010: Capture the Presentation time at the falling edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0011: Capture the Presentation time at both edges of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0100-1000: Reserved - 1001: Toggle output on compare - 1010: Pulse output low on compare for one PTP-clock cycle - 1011: Pulse output high on compare for one PTP-clock cycle

When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

14.20.1.324MAC_PPS0_INTERVAL — Offset 50200B88h

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Bit Range	Default & Access	Field Name (ID): Description
10:8	0h RW	**Time Interval Left Shift Amount (TILS):** This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - . - . - 100: Left shift TI by 7 bits (equal to x128ns) Based on the configuration one or more bits of this field should be treated as Reserved/Read-Only.
7:6	0h RW	**Loop Count to report Scheduling Error (LCSE):** Programmable number of GCL list iterations before reporting an HLBS error defined in EST_Status register. 0x0 (M_4_ITERNS): 4 iterations. 0x1 (M_8_ITERNS): 8 iterations. 0x2 (M_16_ITERNS): 16 iterations. 0x3 (M_32_ITERNS): 32 iterations.
5	0h RW	**Drop Frames causing Scheduling Error (DFBS):** When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_Status register) after 4,8,16,32 (based on LCSE field of this register) GCL iterations are dropped. 0x0 (DONT_DROP): Do not Drop Frames causing Scheduling Error. 0x1 (DROP): Drop Frames causing Scheduling Error.
4	0h RW	**Do not Drop frames during Frame Size Error (DDBF):** When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of EST_Status register). 0x0 (DROP): Drop frames during Frame Size Error. 0x1 (DONT_DROP): Do not Drop frames during Frame Size Error.
3:2	0h RO	**Reserved**
1	0h RW	**Switch to S/W owned list (SSWL):** When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Switch to S/W owned list is disabled. 0x1 (ENABLE): Switch to S/W owned list is enabled.
0	0h RW	**Enable EST (EEST):** When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set. If any uncorrectable error is detected in the EST memory the hardware resets this bit and disables the EST function. 0x0 (DISABLE): EST is disabled. 0x1 (ENABLE): EST is enabled.

14.20.1.344MTL_EST_STATUS — Offset 50200C58h

This register provides Status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Type	Size	Offset	Default
MMIO	32 bit	50200C58h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:20	0h RO	**Reserved**
19:16	0h RO	**Current GCL Slot Number (CGSN):** Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15:8	00h RO	**BTR Error Loop Count (BTRL):** Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "11111111" indicates the iterations exceeded the value of 128 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7	0h RO	**S/W owned list (SWOL):** When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0x0 (INACTIVE): Gate control list number "0" is owned by software. 0x1 (ACTIVE): Gate control list number "1" is owned by software.
6:5	0h RO	**Reserved**
4	0h RW	**Constant Gate Control Error (CGCE):** This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0x0 (INACTIVE): Constant Gate Control Error not detected. 0x1 (ACTIVE): Constant Gate Control Error detected.
3	0h RO	**Head-Of-Line Blocking due to Scheduling (HLBS):** Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. 0x0 (INACTIVE): Head-Of-Line Blocking due to Scheduling not detected. 0x1 (ACTIVE): Head-Of-Line Blocking due to Scheduling detected.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RO	**Head-Of-Line Blocking due to Frame Size (HLBF):** Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros. 0x0 (INACTIVE): Head-Of-Line Blocking due to Frame Size not detected. 0x1 (ACTIVE): Head-Of-Line Blocking due to Frame Size detected.
1	0h RW	**BTR Error (BTRE):** When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "11111111", SWOL is not updated and Software should reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "11111111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0x0 (INACTIVE): BTR Error not detected. 0x1 (ACTIVE): BTR Error detected.
0	0h RW	**Switch to S/W owned list Complete (SWLC):** When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of EST_Control register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0x0 (INACTIVE): Switch to S/W owned list Complete not detected. 0x1 (ACTIVE): Switch to S/W owned list Complete detected.

Note: This bit should always be set as we do not support cut through mode.
0	0h RW	**Flush Transmit Queue (FTQ):** When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights*packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19:14	00h RW	**Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) (RFD):** These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 62: Full minus 32 KB, that is, FULL 32 KB - 63: Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.

7	0h RW	**Enable Hardware Flow Control (EHFC):** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0x0 (DISABLE): Hardware Flow Control is disabled. 0x1 (ENABLE): Hardware Flow Control is enabled.

Bit Range	Default & Access	Field Name (ID): Description
6	0h RW	**Disable Dropping of TCP/IP Checksum Error Packets (DIS_TCP_EF):** When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0x0 (ENABLE): Dropping of TCP/IP Checksum Error Packets is enabled. 0x1 (DISABLE): Dropping of TCP/IP Checksum Error Packets is disabled.
5	0h RW	**Receive Queue Store and Forward (RSF):** When this bit is set, the GbE Controller reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0x0 (DISABLE): Receive Queue Store and Forward is disabled. 0x1 (ENABLE): Receive Queue Store and Forward is enabled.
4	0h RW	**Forward Error Packets (FEP):** When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0x0 (DISABLE): Forward Error Packets is disabled. 0x1 (ENABLE): Forward Error Packets is enabled.
3	0h RW	**Forward Undersized Good Packets (FUP):** When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0x0 (DISABLE): Forward Undersized Good Packets is disabled. 0x1 (ENABLE): Forward Undersized Good Packets is enabled.

This field is ignored when the RSF bit is set to 1. 0x0 (M_64BYTE): 64. 0x1 (M_32BYTE): 32. 0x2 (M_96BYTE): 96. 0x3 (M_128BYTE): 128.

Therefore, the GbE Controller drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0x0 (DISABLE): Receive Queue Packet Arbitration is disabled. 0x1 (ENABLE): Receive Queue Packet Arbitration is enabled.
2:0	0h RW	**Receive Queue Weight (RXQ_WEGT):** This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, i.e. reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.399MTL_TXQ2_LOCREDIT — Offset 50200DA4h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.400MTL_Q2_INTERRUPT_CONTROL_STATUS — Offset 50200DACh

This register contains the interrupt enable and status bits for the queue 2 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.401MTL_RXQ2_OPERATION_MODE — Offset 50200DB0h

The Queue 2 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.402MTL_RXQ2_MISSED_PACKET_OVERFLOW_CNT — Offset 50200DB4h

The Queue 2 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.403MTL_RXQ2_DEBUG — Offset 50200DB8h

The Queue 2 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.404MTL_RXQ2_CONTROL — Offset 50200DBCh

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.405MTL_TXQ3_OPERATION_MODE — Offset 50200DC0h

The Queue 3 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Note: Bit definitions are the same as MTL_TXQ1_OPERATION_MODE, offset 50200D40h.

14.20.1.406MTL_TXQ3_UNDERFLOW — Offset 50200DC4h

The Queue 3 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Note: Bit definitions are the same as MTL_TXQ0_UNDERFLOW, offset 50200D04h.

14.20.1.407MTL_TXQ3_DEBUG — Offset 50200DC8h

The Queue 3 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Note: Bit definitions are the same as MTL_TXQ0_DEBUG, offset 50200D08h.

14.20.1.408MTL_TXQ3_ETS_CONTROL — Offset 50200DD0h

The Queue ETS Control register controls the enhanced transmission selection operation.

Note: Bit definitions are the same as MTL_TXQ1_ETS_CONTROL, offset 50200D50h.

14.20.1.409MTL_TXQ3_ETS_STATUS — Offset 50200DD4h

The Queue 3 ETS Status register provides the average traffic transmitted in Queue 3.

Note: Bit definitions are the same as MTL_TXQ1_ETS_STATUS, offset 50200D54h.

14.20.1.410MTL_TXQ3_QUANTUM_WEIGHT — Offset 50200DD8h

The Queue 3 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 3.

Note: Bit definitions are the same as MTL_TXQ1_QUANTUM_WEIGHT, offset 50200D58h.

14.20.1.411MTL_TXQ3_SENDSLOPECREDIT — Offset 50200DDCh

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_SENDSLOPECREDIT, offset 50200D5Ch.

14.20.1.412MTL_TXQ3_HICREDIT — Offset 50200DE0h

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.413MTL_TXQ3_LOCREDIT — Offset 50200DE4h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.414MTL_Q3_INTERRUPT_CONTROL_STATUS — Offset 50200DECh

This register contains the interrupt enable and status bits for the queue 3 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.415MTL_RXQ3_OPERATION_MODE — Offset 50200DF0h

The Queue 3 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.416MTL_RXQ3_MISSED_PACKET_OVERFLOW_CNT — Offset 50200DF4h

The Queue 3 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.417MTL_RXQ3_DEBUG — Offset 50200DF8h

The Queue 3 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.418MTL_RXQ3_CONTROL — Offset 50200DFCh

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.419MTL_TXQ4_OPERATION_MODE — Offset 50200E00h

The Queue 4 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Note: Bit definitions are the same as MTL_TXQ1_OPERATION_MODE, offset 50200D40h.

14.20.1.420MTL_TXQ4_UNDERFLOW — Offset 50200E04h

The Queue 4 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Note: Bit definitions are the same as MTL_TXQ0_UNDERFLOW, offset 50200D04h.

14.20.1.421MTL_TXQ4_DEBUG — Offset 50200E08h

The Queue 4 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Note: Bit definitions are the same as MTL_TXQ0_DEBUG, offset 50200D08h.

14.20.1.422MTL_TXQ4_ETS_CONTROL — Offset 50200E10h

The Queue ETS Control register controls the enhanced transmission selection operation.

Note: Bit definitions are the same as MTL_TXQ1_ETS_CONTROL, offset 50200D50h.

14.20.1.423MTL_TXQ4_ETS_STATUS — Offset 50200E14h

The Queue 4 ETS Status register provides the average traffic transmitted in Queue 4.

Note: Bit definitions are the same as MTL_TXQ1_ETS_STATUS, offset 50200D54h.

14.20.1.424MTL_TXQ4_QUANTUM_WEIGHT — Offset 50200E18h

The Queue 4 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 4.

Note: Bit definitions are the same as MTL_TXQ1_QUANTUM_WEIGHT, offset 50200D58h.

14.20.1.425MTL_TXQ4_SENDSLOPECREDIT — Offset 50200E1Ch

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_SENDSLOPECREDIT, offset 50200D5Ch.

14.20.1.426MTL_TXQ4_HICREDIT — Offset 50200E20h

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.427MTL_TXQ4_LOCREDIT — Offset 50200E24h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.428MTL_Q4_INTERRUPT_CONTROL_STATUS — Offset 50200E2Ch

This register contains the interrupt enable and status bits for the queue 4 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.429MTL_RXQ4_OPERATION_MODE — Offset 50200E30h

The Queue 4 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.430MTL_RXQ4_MISSED_PACKET_OVERFLOW_CNT — Offset 50200E34h

The Queue 4 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.431MTL_RXQ4_DEBUG — Offset 50200E38h

The Queue 4 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.432MTL_RXQ4_CONTROL — Offset 50200E3Ch

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.433MTL_TXQ5_OPERATION_MODE — Offset 50200E40h

The Queue 5 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Note: Bit definitions are the same as MTL_TXQ1_OPERATION_MODE, offset 50200D40h.

14.20.1.434MTL_TXQ5_UNDERFLOW — Offset 50200E44h

The Queue 5 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Note: Bit definitions are the same as MTL_TXQ0_UNDERFLOW, offset 50200D04h.

14.20.1.435MTL_TXQ5_DEBUG — Offset 50200E48h

The Queue 5 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Note: Bit definitions are the same as MTL_TXQ0_DEBUG, offset 50200D08h.

14.20.1.436MTL_TXQ5_ETS_CONTROL — Offset 50200E50h

The Queue ETS Control register controls the enhanced transmission selection operation.

Note: Bit definitions are the same as MTL_TXQ1_ETS_CONTROL, offset 50200D50h.

14.20.1.437MTL_TXQ5_ETS_STATUS — Offset 50200E54h

The Queue 5 ETS Status register provides the average traffic transmitted in Queue 5.

Note: Bit definitions are the same as MTL_TXQ1_ETS_STATUS, offset 50200D54h.

14.20.1.438MTL_TXQ5_QUANTUM_WEIGHT — Offset 50200E58h

The Queue 5 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 5.

Note: Bit definitions are the same as MTL_TXQ1_QUANTUM_WEIGHT, offset 50200D58h.

14.20.1.439MTL_TXQ5_SENDSLOPECREDIT — Offset 50200E5Ch

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_SENDSLOPECREDIT, offset 50200D5Ch.

14.20.1.440MTL_TXQ5_HICREDIT — Offset 50200E60h

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.441MTL_TXQ5_LOCREDIT — Offset 50200E64h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.442MTL_Q5_INTERRUPT_CONTROL_STATUS — Offset 50200E6Ch

This register contains the interrupt enable and status bits for the queue 5 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.443MTL_RXQ5_OPERATION_MODE — Offset 50200E70h

The Queue 5 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.444MTL_RXQ5_MISSED_PACKET_OVERFLOW_CNT — Offset 50200E74h

The Queue 5 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.445MTL_RXQ5_DEBUG — Offset 50200E78h

The Queue 5 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.446MTL_RXQ5_CONTROL — Offset 50200E7Ch

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.447MTL_TXQ6_OPERATION_MODE — Offset 50200E80h

The Queue 6 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Note: Bit definitions are the same as MTL_TXQ1_OPERATION_MODE, offset 50200D40h.

14.20.1.448MTL_TXQ6_UNDERFLOW — Offset 50200E84h

The Queue 6 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Note: Bit definitions are the same as MTL_TXQ0_UNDERFLOW, offset 50200D04h.

14.20.1.449MTL_TXQ6_DEBUG — Offset 50200E88h

The Queue 6 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Note: Bit definitions are the same as MTL_TXQ0_DEBUG, offset 50200D08h.

14.20.1.450MTL_TXQ6_ETS_CONTROL — Offset 50200E90h

The Queue ETS Control register controls the enhanced transmission selection operation.

Note: Bit definitions are the same as MTL_TXQ1_ETS_CONTROL, offset 50200D50h.

14.20.1.451MTL_TXQ6_ETS_STATUS — Offset 50200E94h

The Queue 6 ETS Status register provides the average traffic transmitted in Queue 6.

Note: Bit definitions are the same as MTL_TXQ1_ETS_STATUS, offset 50200D54h.

14.20.1.452MTL_TXQ6_QUANTUM_WEIGHT — Offset 50200E98h

The Queue 6 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 6.

Note: Bit definitions are the same as MTL_TXQ1_QUANTUM_WEIGHT, offset 50200D58h.

14.20.1.453MTL_TXQ6_SENDSLOPECREDIT — Offset 50200E9Ch

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_SENDSLOPECREDIT, offset 50200D5Ch.

14.20.1.454MTL_TXQ6_HICREDIT — Offset 50200EA0h

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.455MTL_TXQ6_LOCREDIT — Offset 50200EA4h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.456MTL_Q6_INTERRUPT_CONTROL_STATUS — Offset 50200EACh

This register contains the interrupt enable and status bits for the queue 6 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.457MTL_RXQ6_OPERATION_MODE — Offset 50200EB0h

The Queue 6 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.458MTL_RXQ6_MISSED_PACKET_OVERFLOW_CNT — Offset 50200EB4h

The Queue 6 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.459MTL_RXQ6_DEBUG — Offset 50200EB8h

The Queue 6 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.460MTL_RXQ6_CONTROL — Offset 50200EBCh

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.461MTL_TXQ7_OPERATION_MODE — Offset 50200EC0h

The Queue 7 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Note: Bit definitions are the same as MTL_TXQ1_OPERATION_MODE, offset 50200D40h.

14.20.1.462MTL_TXQ7_UNDERFLOW — Offset 50200EC4h

The Queue 7 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Note: Bit definitions are the same as MTL_TXQ0_UNDERFLOW, offset 50200D04h.

14.20.1.463MTL_TXQ7_DEBUG — Offset 50200EC8h

The Queue 7 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Note: Bit definitions are the same as MTL_TXQ0_DEBUG, offset 50200D08h.

14.20.1.464MTL_TXQ7_ETS_CONTROL — Offset 50200ED0h

The Queue ETS Control register controls the enhanced transmission selection operation.

Note: Bit definitions are the same as MTL_TXQ1_ETS_CONTROL, offset 50200D50h.

14.20.1.465MTL_TXQ7_ETS_STATUS — Offset 50200ED4h

The Queue 7 ETS Status register provides the average traffic transmitted in Queue 7.

Note: Bit definitions are the same as MTL_TXQ1_ETS_STATUS, offset 50200D54h.

14.20.1.466MTL_TXQ7_QUANTUM_WEIGHT — Offset 50200ED8h

The Queue 7 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 7.

Note: Bit definitions are the same as MTL_TXQ1_QUANTUM_WEIGHT, offset 50200D58h.

14.20.1.467MTL_TXQ7_SENDSLOPECREDIT — Offset 50200EDCh

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_SENDSLOPECREDIT, offset 50200D5Ch.

14.20.1.468MTL_TXQ7_HICREDIT — Offset 50200EE0h

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_HICREDIT, offset 50200D60h.

14.20.1.469MTL_TXQ7_LOCREDIT — Offset 50200EE4h

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Note: Bit definitions are the same as MTL_TXQ1_LOCREDIT, offset 50200D64h.

14.20.1.470MTL_Q7_INTERRUPT_CONTROL_STATUS — Offset 50200EECh

This register contains the interrupt enable and status bits for the queue 7 interrupts.

Note: Bit definitions are the same as MTL_Q0_INTERRUPT_CONTROL_STATUS, offset 50200D2Ch.

14.20.1.471MTL_RXQ7_OPERATION_MODE — Offset 50200EF0h

The Queue 7 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Note: Bit definitions are the same as MTL_RXQ0_OPERATION_MODE, offset 50200D30h.

14.20.1.472MTL_RXQ7_MISSED_PACKET_OVERFLOW_CNT — Offset 50200EF4h

The Queue 7 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Note: Bit definitions are the same as MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT, offset 50200D34h.

14.20.1.473MTL_RXQ7_DEBUG — Offset 50200EF8h

The Queue 7 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Note: Bit definitions are the same as MTL_RXQ0_DEBUG, offset 50200D38h.

14.20.1.474MTL_RXQ7_CONTROL — Offset 50200EFCh

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Note: Bit definitions are the same as MTL_RXQ0_CONTROL, offset 50200D3Ch.

14.20.1.475DMA_MODE — Offset 50201000h

The Bus Mode register establishes the bus operating modes for the DMA.

17:16	0h RW	**Interrupt Mode (INTM):** This field defines the interrupt mode of GbE Controller. The behavior of the following outputs changes depending on the following settings: - sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) - sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) - sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status. - 00: sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. - 01: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 10: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 11: Reserved 0x0 (MODE0): See above description. 0x1 (MODE1): See above description. 0x2 (MODE2): See above description. 0x3 (RSVD): Reserved.

4:2	0h RW	**Transmit Arbitration Algorithm (TAA):** This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 0x0 (FP): Fixed priority (Channel 0 has the lowest priority and the last channel has the highest priority). 0x1 (WSP): Weighted Strict Priority (WSP). 0x2 (WRR): Weighted Round-Robin (WRR). 0x3 (RSVD): Reserved (for 3'b011 to 3'b111).
1	0h RO	**Reserved**
0	0h RW	**Software Reset (SWR):** When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all GbE Controller clock domains. Before reprogramming any GbE Controller register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Software Reset is disabled. 0x1 (ENABLE): Software Reset is enabled.

14.20.1.476DMA_SYSBUS_MODE — Offset 50201004h

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	0h RW	**Ignore PBL Requirement (IPBL):** When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. 0	0h RW	**Start or Stop Transmission Command (ST):** When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0x0 (STOP): Stop Transmission Command. 0x1 (START): Start Transmission Command.

The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. 0	0h RW	**Enable Slot Comparison (ESC):** When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0x0 (DISABLE): Slot Comparison is disabled. 0x1 (ENABLE): Slot Comparison is enabled.

Bit Range	Default & Access	Field Name (ID): Description
31:12	0h RO	**Reserved**
11:0	000h RO	**ERI Counter (ECNT):** When ERIC bit of DMA_CH(#i)_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter is reset at the start of new packet.

14.20.1.516DMA_CH1_CONTROL — Offset 50201180h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH0_CONTROL, offset 50201100h.

14.20.1.517DMA_CH1_TX_CONTROL — Offset 50201184h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.518DMA_CH1_RX_CONTROL — Offset 50201188h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.519DMA_CH1_TXDESC_LIST_HADDRESS — Offset 50201190h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier. This register must be programmed with desired the higher address before programming the DMA_CHi_TxDesc_List_Address register.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_HADDRESS, offset 50201110h.

14.20.1.520DMA_CH1_TXDESC_LIST_ADDRESS — Offset 50201194h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.521DMA_CH1_RXDESC_LIST_HADDRESS — Offset 50201198h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.522DMA_CH1_RXDESC_LIST_ADDRESS — Offset 5020119Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.523DMA_CH1_TXDESC_TAIL_POINTER — Offset 502011A0h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.524DMA_CH1_RXDESC_TAIL_POINTER — Offset 502011A8h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.525DMA_CH1_TXDESC_RING_LENGTH — Offset 502011ACh

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.526DMA_CH1_RXDESC_RING_LENGTH — Offset 502011B0h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.527DMA_CH1_INTERRUPT_ENABLE — Offset 502011B4h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.528DMA_CH1_RX_INTERRUPT_WATCHDOG_TIMER — Offset 502011B8h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.529DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS — Offset 502011BCh

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.530DMA_CH1_CURRENT_APP_TXDESC — Offset 502011C4h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.531DMA_CH1_CURRENT_APP_RXDESC — Offset 502011CCh

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.532DMA_CH1_CURRENT_APP_TXBUFFER_H — Offset 502011D0h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.533DMA_CH1_CURRENT_APP_TXBUFFER — Offset 502011D4h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.534DMA_CH1_CURRENT_APP_RXBUFFER_H — Offset 502011D8h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.535DMA_CH1_CURRENT_APP_RXBUFFER — Offset 502011DCh

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.536DMA_CH1_STATUS — Offset 502011E0h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.537DMA_CH1_MISS_FRAME_CNT — Offset 502011E4h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.538DMA_CH1_RXP_ACCEPT_CNT — Offset 502011E8h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.539DMA_CH1_RX_ERI_CNT — Offset 502011ECh

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.540DMA_CH2_CONTROL — Offset 50201200h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH0_CONTROL, offset 50201100h.

14.20.1.541DMA_CH2_TX_CONTROL — Offset 50201204h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.542DMA_CH2_RX_CONTROL — Offset 50201208h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.543DMA_CH2_TXDESC_LIST_HADDRESS — Offset 50201210h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier. This register must be programmed with desired the higher address before programming the DMA_CHi_TxDesc_List_Address register.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_HADDRESS, offset 50201110h.

14.20.1.544DMA_CH2_TXDESC_LIST_ADDRESS — Offset 50201214h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.545DMA_CH2_RXDESC_LIST_HADDRESS — Offset 50201218h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.546DMA_CH2_RXDESC_LIST_ADDRESS — Offset 5020121Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.547DMA_CH2_TXDESC_TAIL_POINTER — Offset 50201220h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.548DMA_CH2_RXDESC_TAIL_POINTER — Offset 50201228h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.549DMA_CH2_TXDESC_RING_LENGTH — Offset 5020122Ch

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.550DMA_CH2_RXDESC_RING_LENGTH — Offset 50201230h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.551DMA_CH2_INTERRUPT_ENABLE — Offset 50201234h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.552DMA_CH2_RX_INTERRUPT_WATCHDOG_TIMER — Offset 50201238h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.553DMA_CH2_SLOT_FUNCTION_CONTROL_STATUS — Offset 5020123Ch

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.554DMA_CH2_CURRENT_APP_TXDESC — Offset 50201244h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.555DMA_CH2_CURRENT_APP_RXDESC — Offset 5020124Ch

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.556DMA_CH2_CURRENT_APP_TXBUFFER_H — Offset 50201250h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.557DMA_CH2_CURRENT_APP_TXBUFFER — Offset 50201254h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.558DMA_CH2_CURRENT_APP_RXBUFFER_H — Offset 50201258h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.559DMA_CH2_CURRENT_APP_RXBUFFER — Offset 5020125Ch

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.560DMA_CH2_STATUS — Offset 50201260h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.561DMA_CH2_MISS_FRAME_CNT — Offset 50201264h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.562DMA_CH2_RXP_ACCEPT_CNT — Offset 50201268h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.563DMA_CH2_RX_ERI_CNT — Offset 5020126Ch

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.564DMA_CH3_CONTROL — Offset 50201280h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH0_CONTROL, offset 50201100h.

14.20.1.565DMA_CH3_TX_CONTROL — Offset 50201284h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.566DMA_CH3_RX_CONTROL — Offset 50201288h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.567DMA_CH3_TXDESC_LIST_HADDRESS — Offset 50201290h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. 14.20.1.568DMA_CH3_TXDESC_LIST_ADDRESS — Offset 50201294h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the

corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.569DMA_CH3_RXDESC_LIST_HADDRESS — Offset 50201298h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.570DMA_CH3_RXDESC_LIST_ADDRESS — Offset 5020129Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.571DMA_CH3_TXDESC_TAIL_POINTER — Offset 502012A0h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.572DMA_CH3_RXDESC_TAIL_POINTER — Offset 502012A8h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.573DMA_CH3_TXDESC_RING_LENGTH — Offset 502012ACh

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.574DMA_CH3_RXDESC_RING_LENGTH — Offset 502012B0h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.575DMA_CH3_INTERRUPT_ENABLE — Offset 502012B4h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.576DMA_CH3_RX_INTERRUPT_WATCHDOG_TIMER — Offset 502012B8h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.577DMA_CH3_SLOT_FUNCTION_CONTROL_STATUS — Offset 502012BCh

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.578DMA_CH3_CURRENT_APP_TXDESC — Offset 502012C4h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.579DMA_CH3_CURRENT_APP_RXDESC — Offset 502012CCh

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.580DMA_CH3_CURRENT_APP_TXBUFFER_H — Offset 502012D0h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.581DMA_CH3_CURRENT_APP_TXBUFFER — Offset 502012D4h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.582DMA_CH3_CURRENT_APP_RXBUFFER_H — Offset 502012D8h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.583DMA_CH3_CURRENT_APP_RXBUFFER — Offset 502012DCh

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.584DMA_CH3_STATUS — Offset 502012E0h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.585DMA_CH3_MISS_FRAME_CNT — Offset 502012E4h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.586DMA_CH3_RXP_ACCEPT_CNT — Offset 502012E8h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.587DMA_CH3_RX_ERI_CNT — Offset 502012ECh

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.588DMA_CH4_CONTROL — Offset 50201300h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Type	Size	Offset	Default
MMIO	32 bit	50201300h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31:25	0h RO	**Reserved**
24	0h RW	**Split Headers (SPH):** When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0x0 (DISABLE): Split Headers feature is disabled. 0x1 (ENABLE): Split Headers feature is enabled.
23:21	0h RO	**Reserved**
20:18	0h RW	**Descriptor Skip Length (DSL):** This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17	0h RO	**Reserved**
16	0h RW	**8xPBL mode (PBLX8):** When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0x0 (DISABLE): 8xPBL mode is disabled. 0x1 (ENABLE): 8xPBL mode is enabled.
15:0	0h RO	**Reserved**

14.20.1.589DMA_CH4_TX_CONTROL — Offset 50201304h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.590DMA_CH4_RX_CONTROL — Offset 50201308h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.591DMA_CH4_TXDESC_LIST_HADDRESS — Offset 50201310h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier. This register must be programmed with desired the higher address before programming the DMA_CHi_TxDesc_List_Address register.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_HADDRESS, offset 50201110h.

14.20.1.592DMA_CH4_TXDESC_LIST_ADDRESS — Offset 50201314h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.593DMA_CH4_RXDESC_LIST_HADDRESS — Offset 50201318h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.594DMA_CH4_RXDESC_LIST_ADDRESS — Offset 5020131Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped,

this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.595DMA_CH4_TXDESC_TAIL_POINTER — Offset 50201320h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.596DMA_CH4_RXDESC_TAIL_POINTER — Offset 50201328h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.597DMA_CH4_TXDESC_RING_LENGTH — Offset 5020132Ch

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.598DMA_CH4_RXDESC_RING_LENGTH — Offset 50201330h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.599DMA_CH4_INTERRUPT_ENABLE — Offset 50201334h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.600DMA_CH4_RX_INTERRUPT_WATCHDOG_TIMER — Offset 50201338h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.601DMA_CH4_SLOT_FUNCTION_CONTROL_STATUS — Offset 5020133Ch

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.602DMA_CH4_CURRENT_APP_TXDESC — Offset 50201344h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.603DMA_CH4_CURRENT_APP_RXDESC — Offset 5020134Ch

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.604DMA_CH4_CURRENT_APP_TXBUFFER_H — Offset 50201350h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.605DMA_CH4_CURRENT_APP_TXBUFFER — Offset 50201354h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.606DMA_CH4_CURRENT_APP_RXBUFFER_H — Offset 50201358h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.607DMA_CH4_CURRENT_APP_RXBUFFER — Offset 5020135Ch

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.608DMA_CH4_STATUS — Offset 50201360h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.609DMA_CH4_MISS_FRAME_CNT — Offset 50201364h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.610DMA_CH4_RXP_ACCEPT_CNT — Offset 50201368h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.611DMA_CH4_RX_ERI_CNT — Offset 5020136Ch

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.612DMA_CH5_CONTROL — Offset 50201380h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH4_CONTROL, offset 50201300h.

14.20.1.613DMA_CH5_TX_CONTROL — Offset 50201384h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.614DMA_CH5_RX_CONTROL — Offset 50201388h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.615DMA_CH5_TXDESC_LIST_HADDRESS — Offset 50201390h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier. This register must be programmed with desired the higher address before programming the DMA_CHi_TxDesc_List_Address register.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_HADDRESS, offset 50201110h.

14.20.1.616DMA_CH5_TXDESC_LIST_ADDRESS — Offset 50201394h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.617DMA_CH5_RXDESC_LIST_HADDRESS — Offset 50201398h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.618DMA_CH5_RXDESC_LIST_ADDRESS — Offset 5020139Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.619DMA_CH5_TXDESC_TAIL_POINTER — Offset 502013A0h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.620DMA_CH5_RXDESC_TAIL_POINTER — Offset 502013A8h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.621DMA_CH5_TXDESC_RING_LENGTH — Offset 502013ACh

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.622DMA_CH5_RXDESC_RING_LENGTH — Offset 502013B0h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.623DMA_CH5_INTERRUPT_ENABLE — Offset 502013B4h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.624DMA_CH5_RX_INTERRUPT_WATCHDOG_TIMER — Offset 502013B8h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.625DMA_CH5_SLOT_FUNCTION_CONTROL_STATUS — Offset 502013BCh

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.626DMA_CH5_CURRENT_APP_TXDESC — Offset 502013C4h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.627DMA_CH5_CURRENT_APP_RXDESC — Offset 502013CCh

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.628DMA_CH5_CURRENT_APP_TXBUFFER_H — Offset 502013D0h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.629DMA_CH5_CURRENT_APP_TXBUFFER — Offset 502013D4h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.630DMA_CH5_CURRENT_APP_RXBUFFER_H — Offset 502013D8h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.631DMA_CH5_CURRENT_APP_RXBUFFER — Offset 502013DCh

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.632DMA_CH5_STATUS — Offset 502013E0h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.633DMA_CH5_MISS_FRAME_CNT — Offset 502013E4h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.634DMA_CH5_RXP_ACCEPT_CNT — Offset 502013E8h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.635DMA_CH5_RX_ERI_CNT — Offset 502013ECh

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.636DMA_CH6_CONTROL — Offset 50201400h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH4_CONTROL, offset 50201300h.

14.20.1.637DMA_CH6_TX_CONTROL — Offset 50201404h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.638DMA_CH6_RX_CONTROL — Offset 50201408h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.639DMA_CH6_TXDESC_LIST_HADDRESS — Offset 50201410h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. 14.20.1.641DMA_CH6_RXDESC_LIST_HADDRESS — Offset 50201418h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.642DMA_CH6_RXDESC_LIST_ADDRESS — Offset 5020141Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.643DMA_CH6_TXDESC_TAIL_POINTER — Offset 50201420h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.644DMA_CH6_RXDESC_TAIL_POINTER — Offset 50201428h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.645DMA_CH6_TXDESC_RING_LENGTH — Offset 5020142Ch

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.646DMA_CH6_RXDESC_RING_LENGTH — Offset 50201430h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.647DMA_CH6_INTERRUPT_ENABLE — Offset 50201434h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.648DMA_CH6_RX_INTERRUPT_WATCHDOG_TIMER — Offset 50201438h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.649DMA_CH6_SLOT_FUNCTION_CONTROL_STATUS — Offset 5020143Ch

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.650DMA_CH6_CURRENT_APP_TXDESC — Offset 50201444h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.651DMA_CH6_CURRENT_APP_RXDESC — Offset 5020144Ch

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.652DMA_CH6_CURRENT_APP_TXBUFFER_H — Offset 50201450h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.653DMA_CH6_CURRENT_APP_TXBUFFER — Offset 50201454h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.654DMA_CH6_CURRENT_APP_RXBUFFER_H — Offset 50201458h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.655DMA_CH6_CURRENT_APP_RXBUFFER — Offset 5020145Ch

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.656DMA_CH6_STATUS — Offset 50201460h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.657DMA_CH6_MISS_FRAME_CNT — Offset 50201464h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.658DMA_CH6_RXP_ACCEPT_CNT — Offset 50201468h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.659DMA_CH6_RX_ERI_CNT — Offset 5020146Ch

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

14.20.1.660DMA_CH7_CONTROL — Offset 50201480h

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Note: Bit definitions are the same as DMA_CH4_CONTROL, offset 50201300h.

14.20.1.661DMA_CH7_TX_CONTROL — Offset 50201484h

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Note: Bit definitions are the same as DMA_CH0_TX_CONTROL, offset 50201104h.

14.20.1.662DMA_CH7_RX_CONTROL — Offset 50201488h

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Note: Bit definitions are the same as DMA_CH0_RX_CONTROL, offset 50201108h.

14.20.1.663DMA_CH7_TXDESC_LIST_HADDRESS — Offset 50201490h

The Channeli Tx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Transmit descriptor list. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CHi_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier. This register must be programmed with desired the higher address before programming the DMA_CHi_TxDesc_List_Address register.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_HADDRESS, offset 50201110h.

14.20.1.664DMA_CH7_TXDESC_LIST_ADDRESS — Offset 50201494h

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Note: Bit definitions are the same as DMA_CH0_TXDESC_LIST_ADDRESS, offset 50201114h.

14.20.1.665DMA_CH7_RXDESC_LIST_HADDRESS — Offset 50201498h

The Channeli Rx Descriptor List HAddress register has the higher 8 or 16 bits of the start address of the Receive descriptor list. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the DMA_CHi_RxDesc_List_Address register When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_HADDRESS, offset 50201118h.

14.20.1.666DMA_CH7_RXDESC_LIST_ADDRESS — Offset 5020149Ch

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Note: Bit definitions are the same as DMA_CH0_RXDESC_LIST_ADDRESS, offset 5020111Ch.

14.20.1.667DMA_CH7_TXDESC_TAIL_POINTER — Offset 502014A0h

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_TXDESC_TAIL_POINTER, offset 50201120h.

14.20.1.668DMA_CH7_RXDESC_TAIL_POINTER — Offset 502014A8h

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Note: Bit definitions are the same as DMA_CH0_RXDESC_TAIL_POINTER, offset 50201128h.

14.20.1.669DMA_CH7_TXDESC_RING_LENGTH — Offset 502014ACh

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Note: Bit definitions are the same as DMA_CH0_TXDESC_RING_LENGTH, offset 5020112Ch.

14.20.1.670DMA_CH7_RXDESC_RING_LENGTH — Offset 502014B0h

The Channeli Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Note: Bit definitions are the same as DMA_CH0_RXDESC_RING_LENGTH, offset 50201130h.

14.20.1.671DMA_CH7_INTERRUPT_ENABLE — Offset 502014B4h

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Note: Bit definitions are the same as DMA_CH0_INTERRUPT_ENABLE, offset 50201134h.

14.20.1.672DMA_CH7_RX_INTERRUPT_WATCHDOG_TIMER — Offset 502014B8h

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Note: Bit definitions are the same as DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER, offset 50201138h.

14.20.1.673DMA_CH7_SLOT_FUNCTION_CONTROL_STATUS — Offset 502014BCh

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Note: Bit definitions are the same as DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS, offset 5020113Ch.

14.20.1.674DMA_CH7_CURRENT_APP_TXDESC — Offset 502014C4h

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXDESC, offset 50201144h.

14.20.1.675DMA_CH7_CURRENT_APP_RXDESC — Offset 502014CCh

The Channeli Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXDESC, offset 5020114Ch.

14.20.1.676DMA_CH7_CURRENT_APP_TXBUFFER_H — Offset 502014D0h

The Channeli Current Application Transmit Buffer Address High register has the higher 8 or 16 bits of the current address of the Transmit buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER_H, offset 50201150h.

14.20.1.677DMA_CH7_CURRENT_APP_TXBUFFER — Offset 502014D4h

The Channeli Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_TXBUFFER, offset 50201154h.

14.20.1.678DMA_CH7_CURRENT_APP_RXBUFFER_H — Offset 502014D8h

The Channeli Current Application Receive Buffer Address High register has the higher 8 or 16 bits of the current address of the Receive buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER_H, offset 50201158h.

14.20.1.679DMA_CH7_CURRENT_APP_RXBUFFER — Offset 502014DCh

The Channel 0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Note: Bit definitions are the same as DMA_CH0_CURRENT_APP_RXBUFFER, offset 5020115Ch.

14.20.1.680DMA_CH7_STATUS — Offset 502014E0h

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Note: Bit definitions are the same as DMA_CH0_STATUS, offset 50201160h.

14.20.1.681DMA_CH7_MISS_FRAME_CNT — Offset 502014E4h

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Note: Bit definitions are the same as DMA_CH0_MISS_FRAME_CNT, offset 50201164h.

14.20.1.682DMA_CH7_RXP_ACCEPT_CNT — Offset 502014E8h

The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Note: Bit definitions are the same as DMA_CH0_RXP_ACCEPT_CNT, offset 50201168h.

14.20.1.683DMA_CH7_RX_ERI_CNT — Offset 502014ECh

The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Note: Bit definitions are the same as DMA_CH0_RX_ERI_CNT, offset 5020116Ch.

Bit Range	Default & Access	Field Name (ID): Description
31:12	0h RO	**Reserved**
11	0h RW	**Vc0/1 Wr (IOSF_WR_VC01):** When set, enables VC1 transaction on IOSF AXI Write port. When reset, enables VC0 transaction on IOSF AXI Write port. When RT_Disable fuse is active, this bit is internally tied to '0'.
10	0h RW	**Vc0/1 Rd (IOSF_RD_VC01):** When set, enables VC1 transaction on IOSF AXI Read port. When reset, enables VC0 transaction on IOSF AXI Read port.
9	0h RW	**Write Non Snoop Attribute (WR_NON_SNOOP):** If asserted indicates the transaction from DMA channel0 on IOSF write port is not required to be snooped This bit comes out as req_ns on IOSF master interface. When RT_Disable fuse is active, this bit is internally tied to '0'.
8	0h RW	**Read Non Snoop Attribute (RD_NON_SNOOP):** If asserted indicates the transaction from DMA channel0 on IOSF read port is not required to be snooped This bit comes out as req_ns on IOSF master interface.
7	0h RO	**Reserved**
6:5	0h RO	**Write Root Space (WR_RS):** Root Space attribute for DMA channel0 writes on IOSF. The read value of these bits will always be 00 .
4:3	0h RO	**Read Root Space (RD_RS):** Root Space attribute for DMA channel0 reads on IOSF. The read value of these bits will always be 00 .
2	0h RO	**Reserved**
1:0	0h RW	**DMA Transfer Mode (TRANSFER_MODE):** Indicates mode of transfer for DMA channel0. Four modes are possible: 11 - DRAM to DRAM mode (external, read from DRAM and write to DRAM), 10 - DRAM to SRAM (read from DRAM and write to SRAM), 01 - SRAM to DRAM (read from SRAM and write to DRAM), 00 - SRAM to SRAM (internal, read from SRAM and write to SRAM). In host owned mode, these bits are internally tied to 11 . In proxy mode (when GBE_PROXYMODE bit '0' is set), these bits are internally tied to '00'.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.39 DMA CH6 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH6) — Offset 50210218h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.40 DMA CH7 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH7) — Offset 5021021Ch

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.41 DMA CH8 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH8) — Offset 50210220h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.42 DMA CH9 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH9) — Offset 50210224h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.43 DMA CH10 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH10) — Offset 50210228h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.44 DMA CH11 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH11) — Offset 5021022Ch

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.45 DMA CH12 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH12) — Offset 50210230h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.46 DMA CH13 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH13) — Offset 50210234h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.47 DMA CH14 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH14) — Offset 50210238h

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.48 DMA CH15 Write Address Fillin (IOSF_DEST_ADDR_FILLIN_DMA_CH15) — Offset 5021023Ch

This register defines the upper MSB bits to drive on the IOSF maddr for writes.

Note: Bit definitions are the same as IOSF_ADDR_FILLIN_DMA_CH0, offset 50210100h.

14.20.2.49 D0i3 Control (D0I3C) — Offset 50210410h

This register is will be used for D0i3 SW flow. This will be mapped to a different MMIO address from the other IPC registers. (MMIO and OCP address value are To be done) The description below also includes the type of access expected for the ISH FW for each configuration bit: 1. The Restore Required (RR) bit (bit [3]) should be RW for the ISH FW which can determine when to set and/or clear these bits depending on when the ISH FW determines whether restore is required although for ISH restore is never required since the power is never lost. 2. The D0i3 (i3) bit (bit [2]) should be RO for ISH FW as it needs to be written only by host SW. The ISH FW can determine to go to a low power state based on this bit. 3. The Interrupt Required (IR) bit (bit [1]) can be RO register for ISH FW and ISH FW can send an interrupt to Host by writing to the ish2host IPC doorbell register when this bit is set by SW. 4. The Command in Progress (CIP) register bit (bit [0]) is HW set and need to be cleared by ISH FW (Write 1 to clear). The CIP register bit will be tied to a RTE entry in the IOAPIC as an interrupt source. Hence ISH FW will get an interrupt when the In addition to the registers, the IOSF2OCP Bridge should be parameterized for the following: 1. The device idle capability parameter (ENABLE_PCI_IDLE_CAP) need to be connected to a soft strap for ISH with a value of 1. 2. The STRAP for the MMIO address (strap_d0i3_offset) of D0i3 register (IPC offset address: h6D0) and the d0i3 valid (strap_d0i3_valid) bit needs should be appropriately tied. 3. The PCE register is made RO register by setting the appropriate parameter (Bridge top level strap: set_device_pg_config_type[5:0] is set to all 0s). This registers reset and clock domain will be in the OCP domain.

4	0h RO	**Interrupt Request Capable (IRC):** Set to 1 by HW if it is capable of generating an interrupt on command completion, else 0. For ISH this bit will be tied to 0.
3	1h RW/1C	**Restore Required (RR):** When set (by HW), SW must restore state to the IP. The state may have been lost due to a reset or full power lost. SW clears the bit by writing a 1. This bit will be set on initial power up.
2	0h RW	**D0I3:** SW sets this bit to 1 to move the IP into the D0i3 state. Writing this bit to 0 will return the IP to the fully active D0 state (D0i0).
1	0h RW	**Interrupt Required (IR):** SW sets this bit to 1 to ask for an interrupt to be generated on completion of the command. SW must clear or set this on each write to this register.
0	0h RW/1C	**Command In Progress (CIP):** HW sets this bit on a 1->0 or 0->1 transition of bit [2]. While set, the other bits in this register are not valid and it is illegal for SW to write to any bit in this register. When clear all the other bits in the register are valid and SW may write to any bit.

14.20.3.1 MAC_CONFIGURATION — Offset 50220000h

The MAC Configuration Register establishes the operating mode of the MAC.

Type	Size	Offset	Default
MMIO	32 bit	50220000h	00000000h

Register Level Access:

BIOS Access	SMM Access	OS Access
RW	RW	RW

Bit Range	Default & Access	Field Name (ID): Description
31	0h RW	**ARP Offload Enable (ARPEN):** When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus. This bit is available only when the Enable IPv4 ARP Offload is selected. 0x0 (DISABLE): ARP Offload is disabled. 0x1 (ENABLE): ARP Offload is enabled.
30:28	0h RW	**Source Address Insertion or Replacement Control (SARC):** This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 0x0 (SA_CTRL_IN): mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 0x2 (MAC0_INS_SA): Contents of MAC Addr-0 inserted in SA field. 0x3 (MAC0_REP_SA): Contents of MAC Addr-0 replaces SA field. 0x6 (MAC1_INS_SA): Contents of MAC Addr-1 inserted in SA field. 0x7 (MAC1_REP_SA): Contents of MAC Addr-1 replaces SA field..
27	0h RW	**Checksum Offload (IPC):** When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0x0 (DISABLE): IP header/payload checksum checking is disabled. 0x1 (ENABLE): IP header/payload checksum checking is enabled.

Bit Range	Default & Access	Field Name (ID): Description
26:24	0h RW	**Inter-Packet Gap (IPG):** These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 0x0 (IPG96): 96 bit times IPG. 0x1 (IPG88): 88 bit times IPG. 0x2 (IPG80): 80 bit times IPG. 0x3 (IPG72): 72 bit times IPG. 0x4 (IPG64): 64 bit times IPG. 0x5 (IPG56): 56 bit times IPG. 0x6 (IPG48): 48 bit times IPG. 0x7 (IPG40): 40 bit times IPG.
23	0h RW	**Giant Packet Size Limit Control Enable (GPSLCE):** When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0x0 (DISABLE): Giant Packet Size Limit Control is disabled. 0x1 (ENABLE): Giant Packet Size Limit Control is enabled.
22	0h RW	**IEEE 802.3as Support for 2K Packets (S2KP):** When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0x0 (DISABLE): Support upto 2K packet is disabled. 0x1 (ENABLE): Support upto 2K packet is Enabled.
21	0h RW	**CRC stripping for Type packets (CST):** When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. 0x0 (DISABLE): CRC stripping for Type packets is disabled. 0x1 (ENABLE): CRC stripping for Type packets is enabled.

Bit Range	Default & Access	Field Name (ID): Description
20	0h RW	**Automatic Pad or CRC Stripping (ACS):** When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. 0x0 (DISABLE): Automatic Pad or CRC Stripping is disabled. 0x1 (ENABLE): Automatic Pad or CRC Stripping is enabled..
19	0h RW	**Watchdog Disable (WD):** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0x0 (ENABLE): Watchdog is enabled. 0x1 (DISABLE): Watchdog is disabled.
18	0h RW	**Packet Burst Enable (BE)**: When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0x0 (DISABLE): Packet Burst is disabled. 0x1 (ENABLE): Packet Burst is enabled..
17	0h RW	**Jabber Disable (JD):** When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0x0 (ENABLE): Jabber is enabled. 0x1 (DISABLE): Jabber is disabled.
16	0h RW	**Jumbo Packet Enable (JE):** When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0x0 (DISABLE): Jumbo packet is disabled. 0x1 (ENABLE): Jumbo packet is enabled.
15	0h RW	**Port Select (PS):** This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is readwrite (R/W). 0x0 (M_1000_2500M): For 1000 or 2500 Mbps operations. 0x1 (M_10_100M): For 10 or 100 Mbps operations.
14	0h RW	**FES:** This bit selects the speed mode. 0x0 (M_10_1000M): 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0. 0x1 (M_100_2500M): 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0.

Bit Range	Default & Access	Field Name (ID): Description
13	0h RW	**Duplex Mode (DM):** When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the fullduplex-only configurations. 0x0 (HDUPLX): Half-duplex mode. 0x1 (FDUPLX): Full-duplex mode.
12	0h RW	**Loopback Mode (LM):** When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0x0 (DISABLE): Loopback is disabled. 0x1 (ENABLE): Loopback is enabled.
11	0h RW	**Enable Carrier Sense Before Transmission in Full-Duplex Mode (ECRSFD):** When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0x0 (DISABLE): ECRSFD is disabled. 0x1 (ENABLE): ECRSFD is enabled.
10	0h RW	**Disable Receive Own (DO):** When this bit is set, the MAC disables the reception of packets when the GMII signal TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0x0 (ENABLE): Enable Receive Own. 0x1 (DISABLE): Disable Receive Own.
9	0h RW	**Disable Carrier Sense During Transmission (DCRS)**: When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0x0 (ENABLE): Enable Carrier Sense During Transmission. 0x1 (DISABLE): Disable Carrier Sense During Transmission.
8	0h RW	**Disable Retry (DR):** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0x0 (ENABLE): Enable Retry. 0x1 (DISABLE): Disable Retry.
7	0h RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
6:5	0h RW	**Back-Off Limit (BL):** The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 0x0 (MIN_N_10): k = min(n,10). 0x1 (MIN_N_8): k = min(n,8). 0x2 (MIN_N_4): k = min(n,4). 0x3 (MIN_N_1): k = min(n,1).
4	0h RW	**Deferral Check (DC):** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0x0 (DISABLE): Deferral check function is disabled. 0x1 (ENABLE): Deferral check function is enabled.
3:2	0h RW	**Preamble Length for Transmit packets (PRELEN):** These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 0x0 (M_7BYTES): 7 bytes of preamble. 0x1 (M_5BYTES): 5 bytes of preamble. 0x2 (M_3BYTES): 3 bytes of preamble. 0x3 (RESERVED): Reserved.
1	0h RW	**Transmitter Enable (TE):** When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0x0 (DISABLE): Transmitter is disabled. 0x1 (ENABLE): Transmitter is enabled.
0	0h RW	**Receiver Enable (RE):** When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0x0 (DISABLE): Receiver is disabled. 0x1 (ENABLE): Receiver is enabled.

29:25	00h RW	**Extended Inter-Packet Gap (EIPG):** The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24	0h RW	**Extended Inter-Packet Gap Enable (EIPGEN):** When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There might be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0x0 (DISABLE): Extended Inter-Packet Gap is disabled. 0x1 (ENABLE): Extended Inter-Packet Gap is enabled

19	0h RW	**Packet Duplication Control (PDC):** When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_Address(#i)_High register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of MAC_Address(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0x0 (DISABLE): Packet Duplication Control is disabled. 0x1 (ENABLE): Packet Duplication Control is enabled.
18	0h RW	**Unicast Slow Protocol Packet Detect (USP):** When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0x0 (DISABLE): Unicast Slow Protocol Packet Detection is disabled. 0x1 (ENABLE): Unicast Slow Protocol Packet Detection is enabled.
17	0h RW	**Slow Protocol Detection Enable (SPEN):** When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Slow Protocol Sub-Type and Code fields in Rx status. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0x0 (DISABLE): Slow Protocol Detection is disabled. 0x1 (ENABLE): Slow Protocol Detection is enabled.

16	0h RW	**Disable CRC Checking for Received Packets (DCRCC):** When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0x0 (ENABLE): CRC Checking is enabled. 0x1 (DISABLE): CRC Checking is disabled.
15:14	0h RO	**Reserved**
13:0	0000h RW	**Giant Packet Size Limit (GPSL):** If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

14.20.3.3 MAC_PACKET_FILTER — Offset 50220008h

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

31	0h RW	**Receive All (RA):** When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0x0 (DISABLE): Receive All is disabled. 0x1 (ENABLE): Receive All is enabled.
30:22	0h RO	**Reserved**
21	0h RW	**Drop Non-TCP/UDP over IP Packets (DNTU):** When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0x0 (FWD): Forward Non-TCP/UDP over IP Packets. 0x1 (DROP): Drop Non-TCP/UDP over IP Packets.
20	0h RW	**Layer 3 and Layer 4 Filter Enable (IPFE):** When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0x0 (DISABLE): Layer 3 and Layer 4 Filters are disabled. 0x1 (ENABLE): Layer 3 and Layer 4 Filters are enabled.
19:17	0h RO	**Reserved**
16	0h RW	**VLAN Tag Filter Enable (VTFE):** When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. 15:11	0h RO	**Reserved**
10	0h RW	**Hash or Perfect Filter (HPF):** When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0x0 (DISABLE): Hash or Perfect Filter is disabled. 0x1 (ENABLE): Hash or Perfect Filter is enabled.

Bit Range	Default & Access	Field Name (ID): Description
9	0h RW	**Source Address Filter Enable (SAF):** When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in GbE Controller, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0x0 (DISABLE): SA Filtering is disabled. 0x1 (ENABLE): SA Filtering is enabled.
8	0h RW	**SA Inverse Filtering (SAIF):** When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0x0 (DISABLE): SA Inverse Filtering is disabled. 0x1 (ENABLE): SA Inverse Filtering is enabled.
7:6	0h RW	**Pass Control Packets (PCF):** These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 0x0 (FLTR_ALL): MAC filters all control packets from reaching the application. 0x1 (FW_XCPT_PAU): MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 0x2 (FW_ALL): MAC forwards all control packets to the application even if they fail the Address filter. 0x3 (FW_PASS): MAC forwards the control packets that pass the Address filter.
5	0h RW	**Disable Broadcast Packets (DBF):** When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0x0 (ENABLE): Enable Broadcast Packets. 0x1 (DISABLE): Disable Broadcast Packets.
4	0h RW	**Pass All Multicast (PM):** When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0x0 (DISABLE): Pass All Multicast is disabled. 0x1 (ENABLE): Pass All Multicast is enabled.
3	0h RW	**DA Inverse Filtering (DAIF):** When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0x0 (DISABLE): DA Inverse Filtering is disabled. 0x1 (ENABLE): DA Inverse Filtering is enabled.

Bit Range	Default & Access	Field Name (ID): Description
2	0h RW	**Hash Multicast (HMC):** When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0x0 (DISABLE): Hash Multicast is disabled. 0x1 (ENABLE): Hash Multicast is enabled.
1	0h RW	**Hash Unicast (HUC):** When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0x0 (DISABLE): Hash Unicast is disabled. 0x1 (ENABLE): Hash Unicast is enabled.
0	0h RW	**Promiscuous Mode (PR):** When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0x0 (DISABLE): Promiscuous Mode is disabled. 0x1 (ENABLE): Promiscuous Mode is enabled.

14.20.3.5 MAC_HASH_TABLE_REG0 — Offset 50220010h

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the DA
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted

regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

The Hash Table Register 1 contains the second 32 bits of the hash table. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. 14.20.3.9 MAC_VLAN_HASH_TABLE — Offset 50220058h

When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated hash value are used to index the contents of the VLAN Hash table. For example, hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way:
- Calculate the 32-bit CRC for the VLAN tag or ID
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2. If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] of this register are written. - If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

14.20.3.12 MAC_Q0_TX_FLOW_CTRL — Offset 50220070h

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register. When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. 0	0h RW	**Flow Control Busy or Backpressure Activate (FCB_BPA):** This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0x0 (DISABLE): Flow Control Busy or Backpressure Activate is disabled. 0x1 (ENABLE): Flow Control Busy or Backpressure Activate is enabled.
