You can use several preprocessors in a network analysis policy to detect specific threats to your monitored network, such as Back Orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic. When the GID Signatures specific to pre-processor is enabled, the Network Analysis Policy on Web will show disabled. However, the pre-processors will be turned on device using the available default settings.

You can also use sensitive data detection, which you configure in an intrusion policy, to detect unsecured transmission of sensitive numerical data.

Back Orifice Detection

The Firepower System provides a preprocessor that detects the existence of the Back Orifice program. This program can be used to gain admin access to your Windows hosts.

Back Orifice Detection Preprocessor

The Back Orifice preprocessor analyzes UDP traffic for the Back Orifice magic cookie, "`*!*QWTY?`", which is located in the first eight bytes of the packet and is XOR-encrypted.

The Back Orifice preprocessor has a configuration page, but no configuration options. When it is enabled, you must also enable preprocessor rules for the preprocessor to generate events and, in an inline deployment, drop offending packets.

Table 232: Back Orifice GID:SIDs

Preprocessor rule GID:SID	Description
105:1	Back Orifice traffic detected
105:2	Back Orifice client traffic detected
105:3	Back Orifice server traffic detected
105:4	Back Orifice Snort buffer attack detected

Detecting Back Orifice

Step 1 Choose **Policies** > **Access Control**, then click **Network Analysis Policy** or **Policies** > **Access Control** > **Intrusion**, then click **Network Analysis Policy**.

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

Step 2 Click **Edit** ( ) next to the policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Settings** in the navigation panel.

Step 4 If **Back Orifice Detection** under **Specific Threat Detection** is disabled, click **Enabled**.

Note There are no user-configurable options for Back Orifice.

Step 5 To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable Back Orifice Detection rules 105:1, 105:2, 105:3, or 105:4. For more information, see Intrusion Rule States, on page 1605 and Back Orifice Detection Preprocessor, on page 1892.
- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Portscan Detection

A portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

By itself, a portscan is not evidence of an attack. In fact, some of the portscanning techniques used by attackers can also be employed by legitimate users on your network. Cisco's portscan detector is designed to help you determine which portscans might be malicious by detecting patterns of activity.

Portscan Types, Protocols, and Filtered Sensitivity Levels

Attackers are likely to use several methods to probe your network. Often they use different protocols to draw out different responses from a target host, hoping that if one type of protocol is blocked, another may be available.

Table 233: Protocol Types

Protocol	Description
TCP	Detects TCP probes such as SYN scans, ACK scans, TCP connect() scans, and scans with unusual flag combinations such as Xmas tree, FIN, and NULL
UDP	Detects UDP probes such as zero-byte UDP packets
ICMP	Detects ICMP echo requests (pings)
IP	Detects IP protocol scans. These scans differ from TCP and UDP scans because the attacker, instead of looking for open ports, is trying to discover which IP protocols are supported on a target host.

Portscans are generally divided into four types based on the number of targeted hosts, the number of scanning hosts, and the number of ports that are scanned.

Table 234: Portscan Types

Type	Description
Portscan Detection	A one-to-one portscan in which an attacker uses one or a few hosts to scan multiple ports on a single target host. One-to-one portscans are characterized by: • a low number of scanning hosts • a single host that is scanned • a high number of ports scanned This option detects TCP, UDP, and IP portscans.
Port Sweep	A one-to-many portsweep in which an attacker uses one or a few hosts to scan a single port on multiple target hosts. Portsweeps are characterized by: • a low number of scanning hosts • a high number of scanned hosts • a low number of unique ports scanned This option detects TCP, UDP, ICMP, and IP portsweeps.

Type	Description
Decoy Portscan	A one-to-one portscan in which the attacker mixes spoofed source IP addresses with the actual scanning IP address. Decoy portscans are characterized by: • a high number of scanning hosts • a low number of ports that are scanned only once • a single (or a low number of) scanned hosts The decoy portscan option detects TCP, UDP, and IP protocol portscans.
Distributed Portscan	A many-to-one portscan in which multiple hosts query a single host for open ports. Distributed portscans are characterized by: • a high number of scanning hosts • a high number of ports that are scanned only once • a single (or a low number of) scanned hosts The distributed portscan option detects TCP, UDP, and IP protocol portscans.

The information that the portscan detector learns about a probe is largely based on seeing negative responses from the probed hosts. For example, when a web client tries to connect to a web server, the client uses port 80/tcp and the server can be counted on to have that port open. However, when an attacker probes a server, the attacker does not know in advance if it offers web services. When the portscan detector sees a negative response (that is, an ICMP unreachable or TCP RST packet), it records the response as a potential portscan. The process is more difficult when the targeted host is on the other side of a device such as a firewall or router that filters negative responses. In this case, the portscan detector can generate *filtered* portscan events based on the sensitivity level that you select.

Table 235: Sensitivity Levels

Level	Description
Low	Detects only negative responses from targeted hosts. Select this sensitivity level to suppress false positives, but keep in mind that some types of portscans (slow scans, filtered scans) might be missed. This level uses the shortest time window for portscan detection.

Level	Description
Medium	Detects portscans based on the number of connections to a host, which means that you can detect filtered portscans. However, very active hosts such as network address translators and proxies may generate false positives. Note that you can add the IP addresses of these active hosts to the **Ignore Scanned** field to mitigate this type of false positive. This level uses a longer time window for portscan detection.
High	Detects portscans based on a time window, which means that you can detect time-based portscans. However, if you use this option, you should be careful to tune the detector over time by specifying IP addresses in the **Ignore Scanned** and **Ignore Scanner** fields. This level uses a much longer time window for portscan detection.

Portscan Event Generation

When portscan detection is enabled, you must enable rules with Generator ID (GID) 122 and a Snort ID (SID) from among SIDs 1 through 27 to detect the various portscans and portsweeps.

Note For events generated by the portscan connection detector, the protocol number is set to 255. Because portscan does not have a specific protocol associated with it by default, the Internet Assigned Numbers Authority (IANA) does not have a protocol number assigned to it. IANA designates 255 as a reserved number, so that number is used in portscan events to indicate that there is not an associated protocol for the event.

Table 236: Portscan Detection SIDs (GID 122)

Portscan Type	Protocol	Sensitivity Level	Preprocessor Rule SID
Portscan Detection	TCP	Low	1
	UDP	Medium or High	5
	ICMP	Low	17
	IP	Medium or High	21
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	9
		Medium or High	13

Portscan Type	Protocol	Sensitivity Level	Preprocessor Rule SID
Port Sweep	TCP	Low	3, 27
	UDP	Medium or High	7
	ICMP	Low	19
	IP	Medium or High	23
		Low	25
		Medium or High	26
		Low	11
		Medium or High	15
Decoy Portscan	TCP	Low	2
	UDP	Medium or High	6
	ICMP	Low	18
	IP	Medium or High	22
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	10
		Medium or High	14
Distributed Portscan	TCP	Low	4
	UDP	Medium or High	8
	ICMP	Low	20
	IP	Medium or High	24
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	12
		Medium or High	16

Portscan Event Packet View

When you enable the accompanying preprocessor rules, the portscan detector generates intrusion events that you can view just as you would any other intrusion event. However, the information presented on the packet view is different from the other types of intrusion events.

Begin by using the intrusion event views to drill down to the packet view for a portscan event. Note that you cannot download a portscan packet because single portscan events are based on multiple packets; however, the portscan packet view provides all usable packet information.

For any IP address, you can click the address to view the context menu and select **whois** to perform a lookup on the IP address or **View Host Profile** to view the host profile for that host.

Table 237: Portscan Packet View

Information	Description
Device	The device that detected the event.
Time	The time when the event occurred.
Message	The event message generated by the preprocessor.
Source IP	The IP address of the scanning host.
Destination IP	The IP address of the scanned host.
Priority Count	The number of negative responses (for example, TCP RSTs and ICMP unreachables) from the scanned host. The higher the number of negative responses, the higher the priority count.
Connection Count	The number of active connections on the hosts. This value is more accurate for connection-based scans such as TCP and IP.
IP Count	The number of times that the IP addresses that contact the scanned host changes. For example, if the first IP address is 10.1.1.1, the second IP is 10.1.1.2, and the third IP is 10.1.1.1, then the IP count is 3. This number is less accurate for active hosts such as proxies and DNS servers.
Scanner/Scanned IP Range	The range of IP addresses for the scanned hosts or the scanning hosts, depending on the type of scan. For portsweeps, this field shows the IP range of scanned hosts. For portscans, this shows the IP range of the scanning hosts.
Port/Proto Count	For TCP and UDP portscans, the number of times that the port being scanned changes. For example, if the first port scanned is 80, the second port scanned is 8080, and the third port scanned is again 80, then the port count is 3. For IP protocol portscans, the number of times that the protocol being used to connect to the scanned host changes.
Port/Proto Range	For TCP and UDP portscans, the range of the ports that were scanned. For IP protocol portscans, the range of IP protocol numbers that were used to attempt to connect to the scanned host.
Open Ports	The TCP ports that were open on the scanned host. This field appears only when the portscan detects one or more open ports.

Configuring Portscan Detection

The portscan detection configuration options allow you to finely tune how the portscan detector reports scan activity.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

Step 1 Choose **Policies** > **Access Control**, then click **Network Analysis Policy** or **Policies** > **Access Control** > **Intrusion**, then click **Network Analysis Policy**.

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

Step 2 Click **Edit** ( ) next to the policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Settings**.

Step 4 If **Portscan Detection** under **Specific Threat Detection** is disabled, click **Enabled**.

Step 5 Click **Edit** ( ) next to **Portscan Detection**.

Step 6 In the **Protocol** field, specify protocols to enable.

Note You must ensure TCP stream processing is enabled to detect scans over TCP, and that UDP stream processing is enabled to detect scans over UDP.

Step 7 In the **Scan Type** field, specify portscan types you want to detect.

Step 8 Choose a level from the **Sensitivity Level** list; see Portscan Types, Protocols, and Filtered Sensitivity Levels, on page 1893.

Step 9 If you want to monitor specific hosts for signs of portscan activity, enter the host IP address in the **Watch IP** field.

You can specify a single IP address or address block, or a comma-separated lists of either or both. Leave the field blank to watch all network traffic.

Step 10 If you want to ignore hosts as scanners, enter the host IP address in the **Ignore Scanners** field.

You can specify a single IP address or address block, or a comma-separated lists of either or both.

Step 11 If you want to ignore hosts as targets of a scan, enter the host IP address in the **Ignore Scanned** field.

You can specify a single IP address or address block, or a comma-separated lists of either or both.

Tip Use the **Ignore Scanners** and **Ignore Scanned** fields to indicate hosts on your network that are especially active. You may need to modify this list of hosts over time.

Step 12 If you want to discontinue monitoring of sessions picked up in mid-stream, clear the **Detect Ack Scans** check box.

Note Detection of mid-stream sessions helps to identify ACK scans, but may cause false events, particularly on networks with heavy traffic and dropped packets.

Step 13 To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- If you want portscan detection to detect various portscans and portsweeps, enable rules 122:1 through 122:27. For more information, see Intrusion Rule States, on page 1605 and Portscan Event Generation, on page 1896.
- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Firepower System IP Address Conventions, on page 17

Rate-Based Attack Prevention

Rate-based attacks are attacks that depend on frequency of connection or repeated attempts to perpetrate the attack. You can use rate-based detection criteria to detect a rate-based attack as it occurs and respond to it when it happens, then return to normal detection settings after it stops.

You can configure your network analysis policy to include rate-based filters that detect excessive activity directed at hosts on your network. You can use this feature on managed devices deployed in inline mode to block rate-based attacks for a specified time, then revert to only generating events and not drop traffic.

The SYN attack prevention option helps you protect your network hosts against SYN floods. You can protect individual hosts or whole networks based on the number of packets seen over a period of time. If your device is deployed passively, you can generate events. If your device is placed inline, you can also drop the malicious packets. After the timeout period elapses, if the rate condition has stopped, the event generation and packet dropping stops.

For example, you could configure a setting to allow a maximum number of SYN packets from any one IP address, and block further connections from that IP address for 60 seconds.

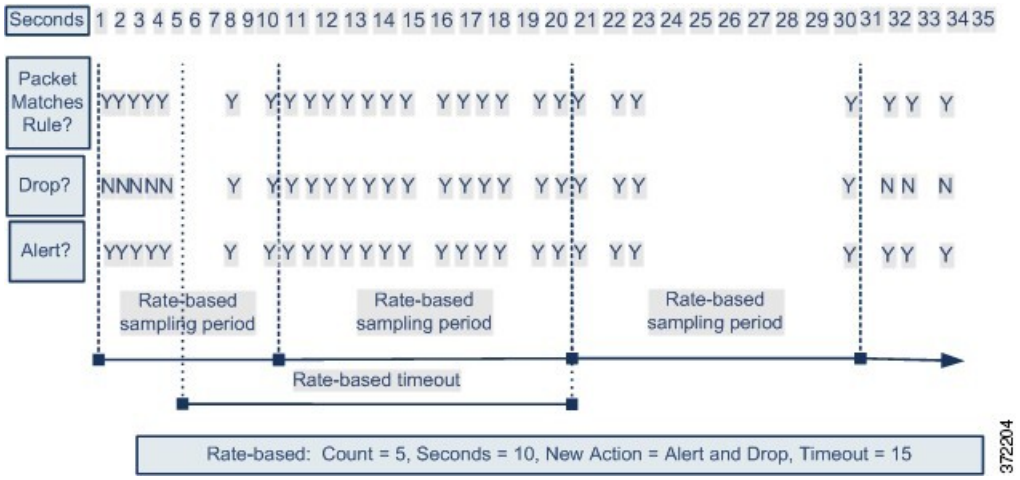
You can also limit TCP/IP connections to or from hosts on your network to prevent denial of service (DoS) attacks or excessive activity by users. When the system detects the configured number of successful connections to or from a specified IP address or range of addresses, it generates events on additional connections. The rate-based event generation continues until the timeout period elapses without the rate condition occurring. In an inline deployment you can choose to drop packets until the rate condition times out.

For example, you could configure a setting to allow a maximum of 10 successful simultaneous connections from any one IP address, and block further connections from that IP address for 60 seconds.

Note Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

The following diagram shows an example where an attacker is attempting to access a host. Repeated attempts to find a password trigger a rule which has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events after rule matches occur five times in a 10-second span. The new rule attribute times out after 15 seconds.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold in the current or previous sampling period, the new action continues. The new action reverts to generating events only after a sampling period completes where the sampled rate is below the threshold rate.



Related Topics

Dynamic Intrusion Rule States, on page 1613

Rate-Based Attack Prevention Examples

The `detection_filter` keyword and the thresholding and suppression features provide other ways to filter either the traffic itself or the events that the system generates. You can use rate-based attack prevention alone or in any combination with thresholding, suppression, or the `detection_filter` keyword.

The `detection_filter` keyword, thresholding or suppression, and rate-based criteria may all apply to the same traffic. When you enable suppression for a rule, events are suppressed for the specified IP addresses even if a rate-based change occurs.

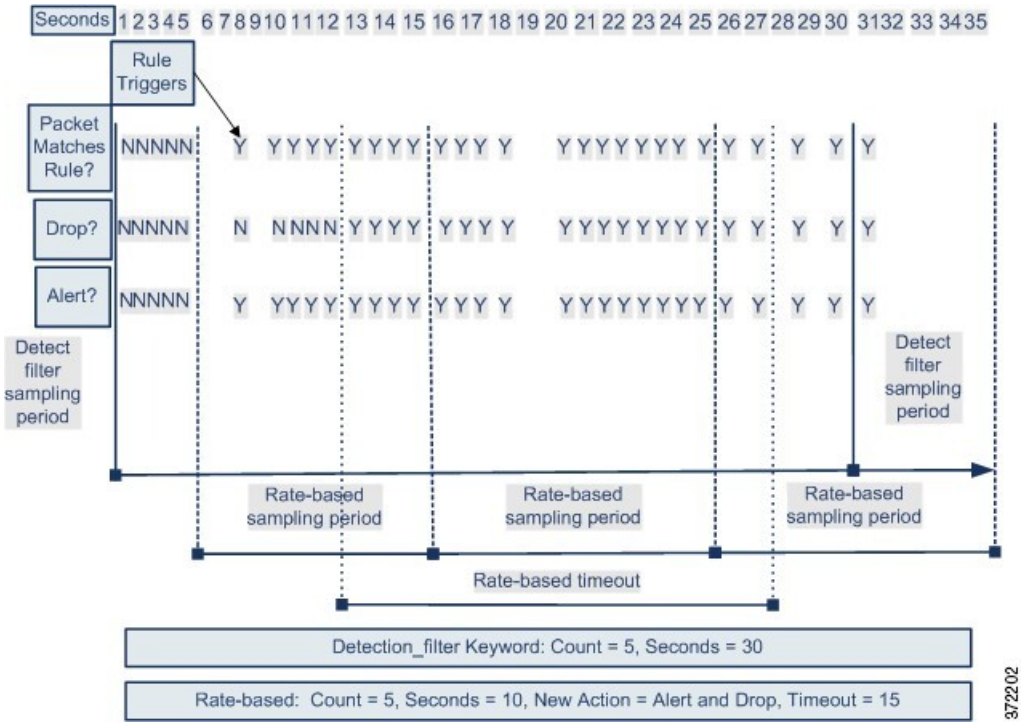
detection_filter Keyword Example

The following example shows an attacker attempting a brute-force login. Repeated attempts to find a password trigger a rule that also includes the `detection_filter` keyword, with a count set to 5. This rule has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events for 20 seconds when there are five hits on the rule in a 10-second span.

As shown in the diagram, the first five packets matching the rule do not generate events because the rule does not trigger until the rate exceeds the rate indicated by the `detection_filter` keyword. After the rule triggers, event notification begins, but the rate-based criteria do not trigger the new action of Drop and Generate Events until five more packets pass.

After the rate-based criteria are met, events are generated and the packets are dropped until the rate-based timeout period expires and the rate falls below the threshold. After twenty seconds elapse, the rate-based action times out. After the timeout, note that packets are still dropped in the rate-based sampling period that

follows. Because the sampled rate is above the threshold rate in the previous sampling period when the timeout happens, the rate-based action continues.



Note that although the example does not depict this, you can use the Drop and Generate Events rule state in combination with the `detection_filter` keyword to start dropping traffic when hits for the rule reach the specified rate. When deciding whether to configure rate-based settings for a rule, consider whether setting the rule to Drop and Generate Events and including the `detection_filter` keyword would achieve the same result, or whether you want to manage the rate and timeout settings in the intrusion policy.

Related Topics

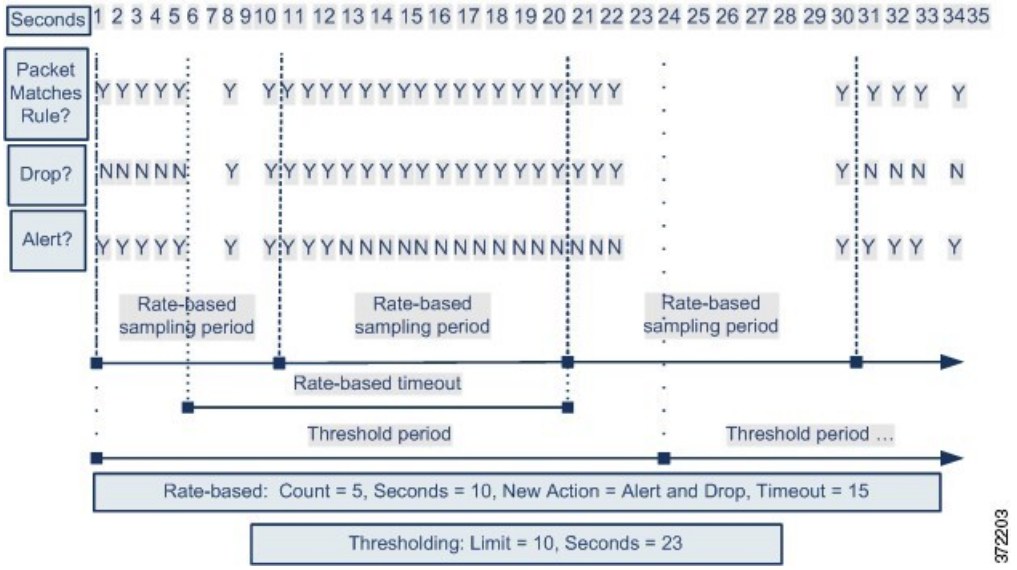
Intrusion Rule States, on page 1605

Dynamic Rule State Thresholding or Suppression Example

The following example shows an attacker attempting a brute-force login. Repeated attempts to find a password trigger a rule that has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events for 15 seconds when there are five hits on the rule in 10 seconds. In addition, a limit threshold limits the number of events the rule can generate to 10 events in 23 seconds.

As shown in the diagram, the rule generates events for the first five matching packets. After five packets, the rate-based criteria trigger the new action of Drop and Generate Events, and for the next five packets the rule generates events and the system drops the packet. After the tenth packet, the limit threshold has been reached, so for the remaining packets the system does not generate events but does drop the packets.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold rate in the current or previous sampling period, the new action continues. The new action reverts to Generate Events only after a sampling period completes where the sampled rate is below the threshold rate.



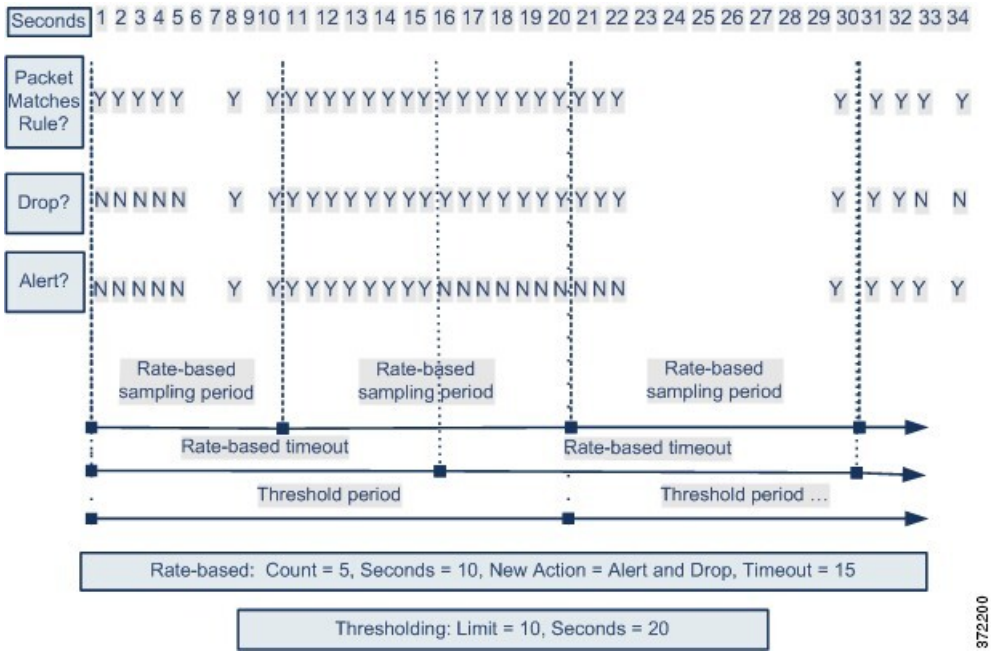
Note that although it is not shown in this example, if a new action triggers because of rate-based criteria *after* a threshold has been reached, the system generates a single event to indicate the change in action. So, for example, when the limit threshold of 10 is reached and the system stops generating events and the action changes from Generate Events to Drop and Generate Events on the 14th packet, the system generates an eleventh event to indicate the change in action.

Policy-Wide Rate-Based Detection and Thresholding or Suppression Example

The following example shows an attacker attempting denial of service (DoS) attacks on hosts in your network. Many simultaneous connections to hosts from the same sources trigger a policy-wide Control Simultaneous Connections setting. The setting generates events and drops malicious traffic when there are five connections from one source in 10 seconds. In addition, a global limit threshold limits the number of events any rule or setting can generate to 10 events in 20 seconds.

As shown in the diagram, the policy-wide setting generates events for the first ten matching packets and drops the traffic. After the tenth packet, the limit threshold is reached, so for the remaining packets no events are generated but the packets are dropped.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold rate in the current or previous sampling period, the rate-based action of generating events and dropping traffic continues. The rate-based action stops only after a sampling period completes where the sampled rate is below the threshold rate.



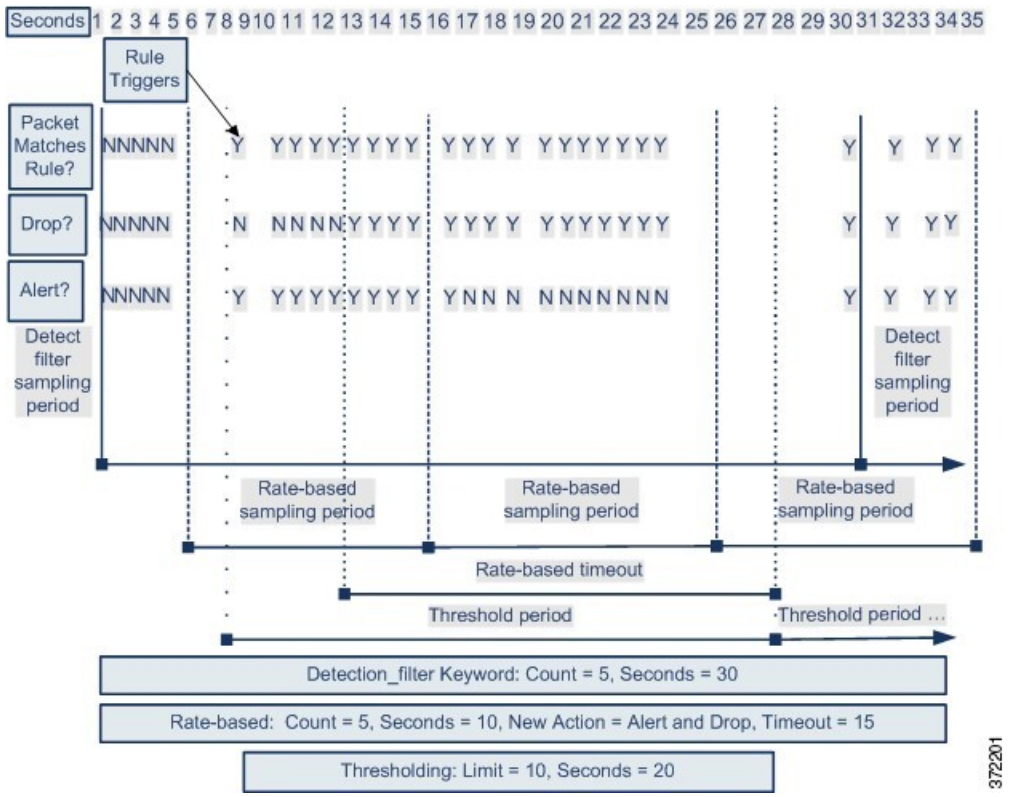
Note that although it is not shown in this example, if a new action triggers because of rate-based criteria *after* a threshold has been reached, the system generates a single event to indicate the change in action. So, for example, if the limit threshold of 10 has been reached and the system stops generating events and the action changes to Drop and Generate events on the 14th packet, the system generates an eleventh event to indicate the change in action.

Rate-Based Detection with Multiple Filtering Methods Example

The following example shows an attacker attempting a brute force login, and describes a case where a `detection_filter` keyword, rate-based filtering, and thresholding interact. Repeated attempts to find a password trigger a rule which includes the `detection_filter` keyword, with a count set to 5. This rule also has rate-based attack prevention settings that change the rule attribute to Drop and Generate Events for 30 seconds when there are five rule hits in 15 seconds. In addition, a limit threshold limits the rule to 10 events in 30 seconds.

As shown in the diagram, the first five packets matching the rule do not cause event notification because the rule does not trigger until the rate indicated in the `detection_filter` keyword is exceeded. After the rule triggers, event notification begins, but the rate-based criteria do not trigger the new action of Drop and Generate Events until five more packets pass. After the rate-based criteria are met, the system generates events for packets 11-15 and drops the packets. After the fifteenth packet, the limit threshold has been reached, so for the remaining packets the system does not generate events but does drop the packets.

After the rate-based timeout, note that packets are still dropped in the rate-based sampling period that follows. Because the sampled rate is above the threshold rate in the previous sampling period, the new action continues.



Rate-Based Attack Prevention Options and Configuration

Rate-based attack prevention identifies abnormal traffic patterns and attempts to minimize the impact of that traffic on legitimate requests. Rate-based attacks usually have one of the following characteristics:

- Any traffic containing excessive incomplete connections to hosts on the network, indicating a SYN flood attack
- Any traffic containing excessive complete connections to hosts on the network, indicating a TCP/IP connection flood attack
- Excessive rule matches in traffic going to a particular destination IP address or addresses or coming from a particular source IP address or addresses
- Excessive matches for a particular rule across all traffic

In a network analysis policy, you can either configure SYN flood or TCP/IP connection flood detection for the entire policy; in an intrusion policy, you can set rate-based filters for individual intrusion or preprocessor rules. Note that you cannot manually add a rate-based filter to GID 135 rules or modify their rule state. Rules with GID 135 use the client as the source value and the server as the destination value.

When**SYN Attack Prevention** is enabled, rule 135:1 triggers if a defined rate condition is exceeded.

When **Control Simultaneous Connections** is enabled, rule 135:2 tiggers if a defined rate condition is exceeded, and rule 135:3 triggeres if a session closes or times out.

Note Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

Each rate-based filter contains several components:

- For policy-wide or rule-based source or destination settings, the network address designation
- The rule matching rate, which you configure as a count of rule matches within a specific number of seconds
- A new action to be taken when the rate is exceeded

  When you set a rate-based setting for the entire policy, the system generates events when it detects a rate-based attack, and can drop the traffic in an inline deployment. When setting rate-based actions for individual rules, you have three available actions: Generate Events, Drop and Generate Events, and Disable.
- The duration of the action, which you configure as a timeout value

Note that when started, the new action occurs until the timeout is reached, even if the rate falls below the configured rate during that time period. When the timeout period expires, if the rate has fallen below the threshold, the action for the rule reverts to the action initially configured for the rule. For policy-wide settings, the action reverts to the action of each rule the traffic matches or stops if it does not match any rules.

You can configure rate-based attack prevention in an inline deployment to block attacks, either temporarily or permanently. Without rate-based configuration, rules set to Generate Events create events, but the system does not drop packets for those rules. However, if the attack traffic matches rules that have rate-based criteria configured, the rate action may cause packet dropping to occur for the period of time that the rate action is active, even if those rules are not initially set to Drop and Generate Events.

Note Rate-based actions cannot enable disabled rules or drop traffic that matches disabled rules. However, if you set a rate-based filter at the policy level, you can generate events on or generate events on and drop traffic that contains an excessive number of SYN packets or SYN/ACK interactions within a designated time period.

You can define multiple rate-based filters on the same rule. The first filter listed in the intrusion policy has the highest priority. Note that when two rate-based filter actions conflict, the system implements the action of the first rate-based filter. Similarly, policy-wide rate-based filters override rate-based filters set on individual rules if the filters conflict.

Related Topics

Setting a Dynamic Rule State from the Rules Page, on page 1614

Rate-Based Attack Prevention, Detection Filtering, and Thresholding or Suppression

The `detection_filter` keyword prevents a rule from triggering until a threshold number of rule matches occur within a specified time. When a rule includes the `detection_filter` keyword, the system tracks the number of incoming packets matching the pattern in the rule per timeout period. The system can count hits

for that rule from particular source or destination IP addresses. After the rate exceeds the rate in the rule, event notification for that rule begins.

You can use thresholding and suppression to reduce excessive events by limiting the number of event notifications for a rule, a source, or destination, or by suppressing notifications altogether for that rule. You can also configure a global rule threshold that applies to each rule that does not have an overriding specific threshold.

If you apply suppression to a rule, the system suppresses event notifications for that rule for all applicable IP addresses even if a rate-based action change occurs because of a policy-wide or rule-specific rate-based setting.

Global Rule Thresholding Basics, on page 1637

Configuring Rate-Based Attack Prevention

You can configure rate-based attack prevention at the policy level to stop SYN flood attacks. You can also stop excessive connections from a specific source or to a specific destination.

Step 1 Choose **Policies** > **Access Control**, then click **Network Analysis Policy** or **Policies** > **Access Control** > **Intrusion**, then click **Network Analysis Policy**.

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

Step 2 Click **Edit** ( ) next to the policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Settings**.

Step 4 If **Rate-Based Attack Prevention** under **Specific Threat Detection** is disabled, click **Enabled**.

Step 5 Click **Edit** ( ) next to **Rate-Based Attack Prevention**.

Step 6 You have two choices:

- To prevent incomplete connections intended to flood a host, click **Add** under **SYN Attack Prevention**.
- To prevent excessive numbers of connections, click **Add** under **Control Simultaneous Connections**.

Step 7 Specify how you want to track traffic:

- To track all traffic from a specific source or range of sources, choose **Source** from the **Track By** drop-down list, and enter a single IP address or address block in the **Network** field.
- To track all traffic to a specific destination or range of destinations, choose **Destination** from the **Track By** drop-down list, and enter an IP address or address block in the **Network** field.

Note

- Do not enter the IP address 0.0.0.0/0 in the Network field to monitor all subnets or IPs. The system does not support this IP address (which is usually used to identify all subnets or IPs) for Rate Based Attack Prevention.
- The system tracks traffic separately for each IP address included in the **Network** field. Traffic from an IP address that exceeds the configured rate results in generated events only for that IP address. As an example, you might set a source CIDR block of `10.1.0.0/16` for the network setting and configure the system to generate events when there are ten simultaneous connections open. If eight connections are open from 10.1.4.21 and six from 10.1.5.10, the system does not generate events, because neither source has the triggering number of connections open. However, if eleven simultaneous connections are open from 10.1.4.21, the system generates events only for the connections from 10.1.4.21.

  The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

Step 8 Specify the triggering rate for the rate tracking setting:

- For SYN attack configuration, enter the number of SYN packets per number of seconds in the **Rate** fields.
- For simultaneous connection configuration, enter the number of connections in the **Count** field.

Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

Step 9 To drop packets matching the rate-based attack prevention settings, check the **Drop** check box.

Step 10 In the **Timeout** field, enter the time period after which to stop generating events (and if applicable, dropping) for traffic with the matching pattern of SYNs or simultaneous connections.

Caution Setting a high timeout value may entirely block connection to a host in an inline deployment.

Step 11 Click **OK**.

Step 12 To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

CHAPTER 91

Adaptive Profiles

The following topics describe how to configure adaptive profiles:

About Adaptive Profiles

Adaptive profiles must be enabled in order to:

- Perform application and file control, including malware protection (AMP), and to allow intrusion rules to use service metadata.

Caution Adaptive profiling **must** be enabled (its default state) as described in Configuring Adaptive Profiles, on page 1912 for access control rules to perform application and file control, including malware protection (AMP), and for intrusion rules to use service metadata.

- For passive deployments, enable adaptive profile updates to defragment and reassemble IP traffic according to the destination hosts' operating systems.

Note For inline deployments Cisco recommends that, instead of enabling adaptive profile updates, you configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

Adaptive Profile Updates

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party.

Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host.

Manually configured target-based profiles apply either the default operating system profile you select, or profiles you bind to specific hosts. Profile updates, however, switch to the appropriate operating system profile based on the operating system in the host profile for the target host.

Consider a scenario where you configure profile updates for the 10.6.0.0/16 subnet and set the default IP Defragmentation target-based policy to Linux. The Firepower Management Center where you configure the settings has a network map that includes the 10.6.0.0/16 subnet.

- When the system detects traffic from Host A, which is not in the 10.6.0.0/16 subnet, it uses the Linux target-based policy to reassemble IP fragments.

- When the system detects traffic from Host B, which is in the 10.6.0.0/16 subnet, it retrieves Host B's operating system data from the network map. The system uses a profile based on that operating system to defragment the traffic destined for Host B.

Adaptive Profile Updates and Firepower Recommended Rules

The adaptive profile updates feature is an advanced setting in an access control policy that applies globally to all intrusion policies invoked by that access control policy. The Firepower recommended rules feature applies to the individual intrusion policy where you configure it.

Like Firepower recommended rules, profile updates compare metadata in a rule to host information to determine whether a rule should apply for a particular host. However, while Firepower recommended rules provide recommendations for enabling or disabling rules using that information, profile updates use the information to apply specific rules to specific traffic.

Firepower recommended rules require your interaction to implement suggested changes to rule states. Profile updates, on the other hand, do not modify intrusion policies. Treatment of rules based on profile updates happens on a packet-by-packet basis.

Additionally, Firepower recommended rules can result in enabling disabled rules. Profile updates, in contrast, only affect the application of rules that are already enabled in intrusion policies. Profile updates never change the rule state.

You can use profile updates and Firepower recommended rules in combination. Profile updates use the rule state for a rule when your intrusion policy is deployed to determine whether to include it as a candidate for applying, and your choices to accept or decline recommendations are reflected in that rule state. You can use both features to ensure that you have enabled or disabled the most appropriate rules for each network you monitor, and then to apply enabled rules most efficiently for specific traffic.

About Firepower Recommended Rules, on page 1617

Adaptive Profile Options

Enable

Enabling this option is required for:

- access control rules to perform application and file control, including malware protection (AMP)
- intrusion rules to use service metadata

This option is enabled by default.

Enable Profile Updates

In passive deployments, enable profile updates to defragment and reassemble IP traffic according to a profile of the operating system used by the hosts in your network map

Adaptive Profiles - Attribute Update Interval

When profile updates are enabled, you can control how frequently in minutes network map data is synced from the Firepower Management Center to its managed devices. The system uses the data to determine what profiles should be used when processing traffic. Increasing the value for this option can improve performance in a large network.

Adaptive Profiles - Networks

Optionally, when profile updates are enabled, you can improve performance by constraining profile updates to a comma-separated list of IP addresses, address blocks, and network variables. If you use a network variable, the system uses the variable's value in the variable set linked to the default intrusion policy for your access control policy. For example, you could enter: **`192.168.1.101, 192.168.4.0/24, $HOME_NET`**. IPv4 and IPv6 are supported.

The default value (**`0.0.0.0/0`**) applies adaptive profile updates to all networks.

Note The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. If you enable and enforce profile updates in an ancestor policy, Cisco recommends you keep the default network constraint of **`0.0.0.0/0`**, or use a network variable with a value of `any` . This setting applies profile updates to all monitored hosts in all subdomains.

Firepower System IP Address Conventions, on page 17
Variable Sets, on page 442

Configuring Adaptive Profiles

In a passive deployment, Cisco recommends that you configure adaptive profile updates. In an inline deployment, configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

Caution Adaptive profiling **must** be enabled (its default state) as described in this procedure for access control rules to perform application or file control, including AMP, and for intrusion rules to use service metadata.

Before you begin

The access control policy must have a network discovery policy that is enabled to do host/service discovery, or host data must be imported from a third-party source.

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Detection Enhancement Settings section.

If **View** (🔍) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Set adaptive profile options as described in Adaptive Profile Options, on page 1911.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

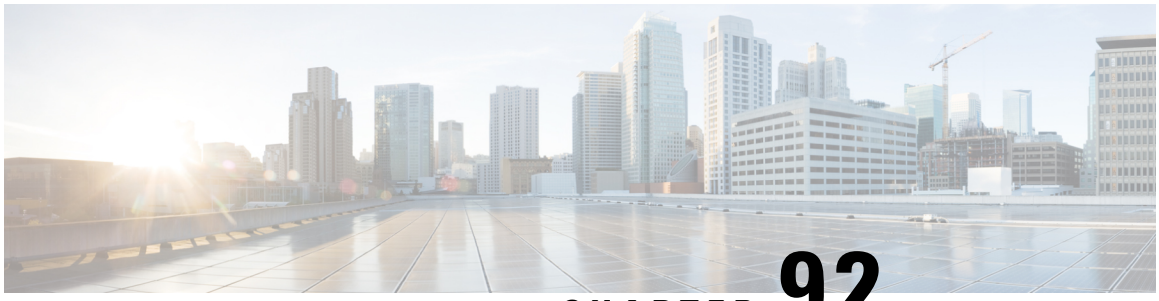
PART XX

Discovery and Identity



CHAPTER 92

Introduction to Network Discovery and Identity

The following topics provide an introduction to network discovery and identity policies and data:

About Detection of Host, Application, and User Data

The Firepower System uses *network discovery* and *identity* policies to collect host, application, and user data for traffic on your network. You can use certain types of discovery and identity data to build a comprehensive map of your network assets, perform forensic analysis, behavioral profiling, access control, and mitigate and respond to the vulnerabilities and exploits to which your organization is susceptible.

Host and Application Data

Host and application data is collected by host identity sources and application detectors according to the settings in your network discovery policy. Managed devices observe traffic on the network segments you specify.

For more information, see Host and Application Detection Fundamentals, on page 1918.

User Data

User data is collected by user identity sources according to the settings in your network discovery and identity policies. You can use the data for user awareness and user control.

For more information, see About User Identity, on page 1925.

Logging discovery and identity data allows you to take advantage of many features in the Firepower System, including:

- Viewing the network map, which is a detailed representation of your network assets and topology that you can view by grouping hosts and network devices, host attributes, application protocols, or vulnerabilities.
- Performing application and user control; that is, writing access control rules using application, realm, user, user group, and ISE attribute conditions.
- Viewing host profiles, which are complete views of all the information available for your detected hosts.

- Viewing dashboards, which (among other capabilities) can provide you with an at-a-glance view of your network assets and user activity.
- Viewing detailed information on the discovery events and user activity logged by the system.
- Associating hosts and any servers or clients they are running with the exploits to which they are susceptible.

  This enables you to identify and mitigate vulnerabilities, evaluate the impact that intrusion events have on your network, and tune intrusion rule states so that they provide maximum protection for your network assets
- Alerting you by email, SNMP trap, or syslog when the system generates either an intrusion event with a specific impact flag, or a specific type of discovery event
- Monitoring your organization's compliance with a white list of allowed operating systems, clients, application protocols, and protocols
- Creating correlation policies with rules that trigger and generate correlation events when the system generates discovery events or detects user activity
- Logging and using NetFlow connections, if applicable.

User Identity Sources

Host and Application Detection Fundamentals

You can configure your network discovery policy to perform host and application detection.

For more information, see Overview: Host Data Collection, on page 1937 and Overview: Application Detection, on page 1975.

Passive Detection of Operating System and Host Data

Passive detection is the system's default method of populating the network map by analyzing network traffic (and any exported NetFlow data). Passive detection provides contextual information about your network assets, such as operating systems and running applications.

If traffic from a monitored host does not offer conclusive evidence of the host's operating system, the network map displays the most likely operating system. For example, a NAT device may appear to be running several operating systems because of the hosts "behind" the NAT device. To make this most-likely determination, the system uses a confidence value it assigns to each detected operating system, and the amount of corroborating data among detected operating systems.

Note The system does not consider reported "`unknown`" applications and operating systems in its determination.

If passive detection inaccurately identifies your network assets, consider the placement of your managed devices. You can also augment the system's passive detection capabilities with custom operating-system fingerprints and custom application detectors. Or, you can use *active detection*, which is not based on traffic

analysis, but instead allows you to directly update the network map using scan results or other information sources.

Active Detection of Operating System and Host Data

Active detection adds host information collected by active sources to network maps. For example, you can use the Nmap scanner to actively scan the hosts that you target on your network. Nmap discovers operating systems and applications on hosts.

In addition, the host input feature allows you to actively add *host input data* to network maps. There are two different categories of host input data:

- *user input data*—Data added through the Firepower System user interface. You can modify a host's operating system or application identity through this interface.
- *host import input data*—Data imported using a command line utility.

The system retains one identity for each active source. When you run an Nmap scan instance, for example, the results of the previous scan are replaced with the new scan results. However, if you run an Nmap scan and then replace those results with data from a client whose results are imported through the command line, the system retains both the identities from the Nmap results and the identities from the import client. The system then uses the priorities set in the network discovery policy to determine which active identity to use as the current identity.

Note that user input is considered one source, even if it comes from different users. As an example, if UserA sets the operating system through the host profile, and then UserB changes that definition through the host profile, the definition set by UserB is retained, and the definition set by UserA is discarded. In addition, note that user input overrides all other active sources and is used as the current identity if it exists.

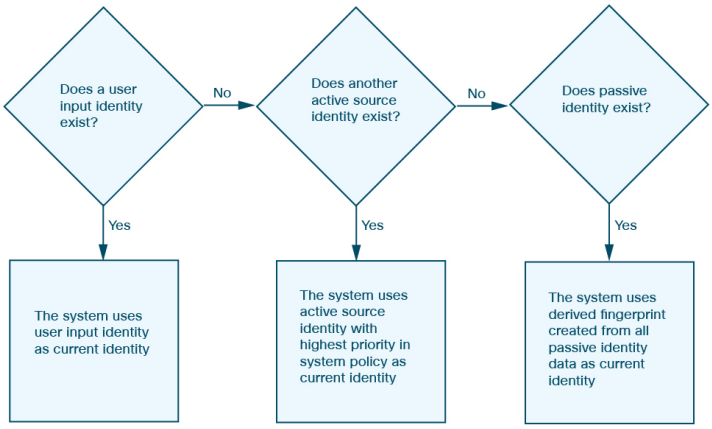
Current Identities for Applications and Operating Systems

The *current identity* for an application or an operating system on a host is the identity that the system finds most likely to be correct.

The system uses the current identity for an operating system or application for the following purposes:

- to assign vulnerabilities to a host
- for impact assessment
- when evaluating correlation rules written against operating system identifications, host profile qualifications, and compliance white lists
- for display in the Hosts and Servers table views in workflows
- for display in the host profile
- to calculate the operating system and application statistics on the Discovery Statistics page

The system uses source priorities to determine which active identity should be used as the current identity for an application or operating system.



For example, if a user sets the operating system to Windows 2003 Server on a host, Windows 2003 Server is the current identity. Attacks which target Windows 2003 Server vulnerabilities on that host are given a higher impact, and the vulnerabilities listed for that host in the host profile include Windows 2003 Server vulnerabilities.

The database may retain information from several sources for the operating system or for a particular application on a host.

The system treats an operating system or application identity as the current identity when the source for the data has the highest source priority. Possible sources have the following priority order:

1. user

2. scanner and application (set in the network discovery policy)

3. managed devices

4. NetFlow records

A new higher priority application identity will not override a current application identity if it has less detail than the current identity.

In addition, when an identity conflict occurs, the resolution of the conflict depends on settings in the network discovery policy or on your manual resolution.

Current User Identities

When the system detects multiple logins to the same host by different users, the system assumes that only one user is logged into any given host at a time, and that the current user of a host is the last authoritative user login. If only non-authoritative user logins have been logged into the host, the last non-authoritative user login is considered the current user. If multiple users are logged in through remote sessions, the last user reported by the server is the user reported to the Firepower Management Center.

When the system detects multiple logins to the same host by the same user, the system records the first time that a user logs into a specific host and disregards subsequent logins. If an individual user is the only person who logs into a specific host, the only login that the system records is the original login.

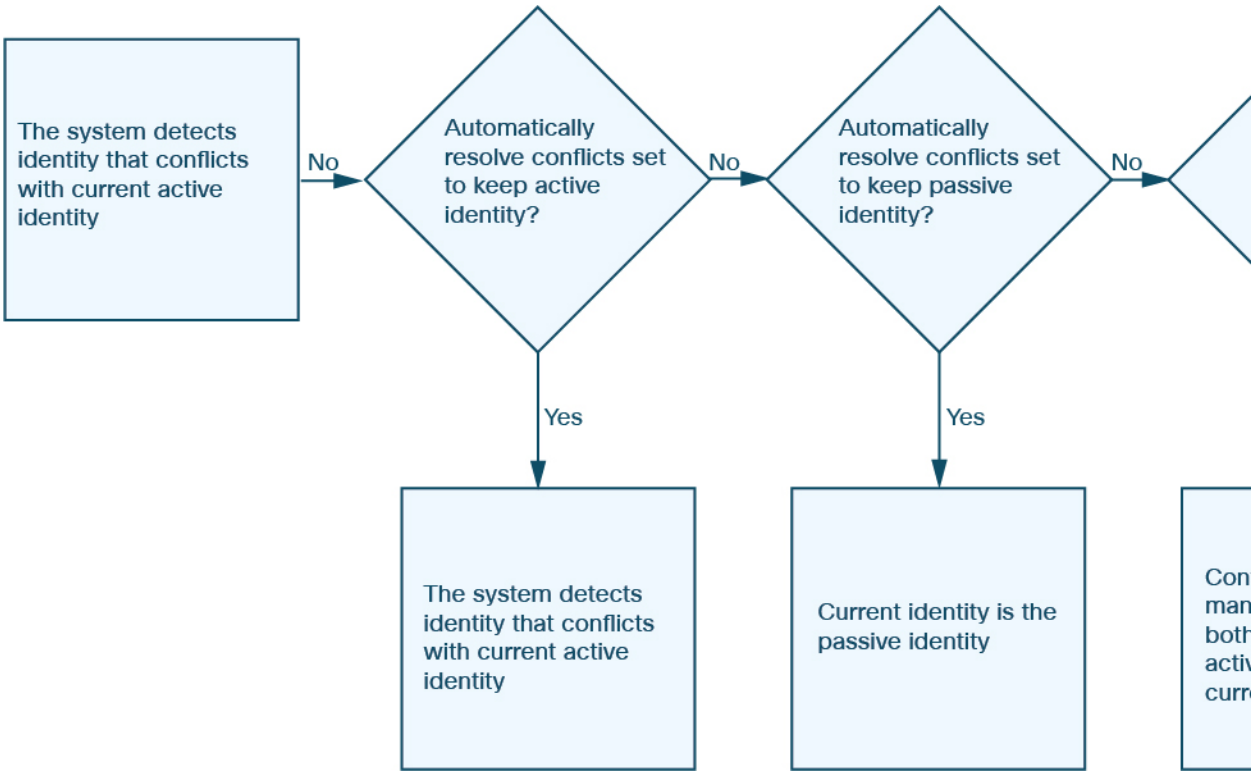
If another user logs into that host, however, the system records the new login. Then, if the original user logs in again, his or her new login is recorded.

Application and Operating System Identity Conflicts

An *identity conflict* occurs when the system reports a new passive identity that conflicts with the current active identity and previously reported passive identities. For example, the previous passive identity for an operating system is reported as Windows 2000, then an active identity of Windows XP becomes current. Next, the system detects a new passive identity of Ubuntu Linux 8.04.1. The Windows XP and the Ubuntu Linux identities are in conflict.

When an identity conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists both conflicting identities as current and uses both for impact assessment until the conflict is resolved.

A user with Administrator privileges can resolve identity conflicts automatically by choosing to always use the passive identity or always use the active identity. Unless you disable automatic resolution of identity conflicts, identity conflicts are always automatically resolved.



A user with Administrator privileges can also configure the system to generate an event when an identity conflict occurs. That user can then set up a correlation policy with a correlation rule that uses an Nmap scan as a correlation response. When an event occurs, Nmap scans the host to obtain updated host operating system and application data.

Netflow Data in the Firepower System

NetFlow is a Cisco IOS application that provides statistics on packets flowing through a router. It is available on Cisco networking devices and can also be embedded in Juniper, FreeBSD, and OpenBSD devices.

When NetFlow is enabled on a network device, a database on the device (the NetFlow cache) stores records of the flows that pass through the router. A flow, called a *connection* in the Firepower System, is a sequence

of packets that represents a session between a source and destination host, using specific ports, protocol, and application protocol. The network device can be configured to export this NetFlow data. In this documentation, network devices configured in this way are called *NetFlow exporters*.

Firepower System managed devices can be configured to collect records from NetFlow exporters, generate unidirectional end-of-connection events based on the data in those records, and finally send those events to the Firepower Management Center to be logged in the connection event database. You can also configure the network discovery policy to add host and application protocol information to the database based on the information in NetFlow connections.

You can use this discovery and connection data to supplement the data gathered directly by your managed devices. This is especially useful if you have NetFlow exporters monitoring networks that your managed devices cannot monitor.

Requirements for Using NetFlow Data

Before you configure the Firepower System to analyze NetFlow data, you must enable the NetFlow feature on the routers or other NetFlow-enabled network devices you plan to use, and configure the devices to broadcast NetFlow data to a destination network where the sensing interface of a managed device is connected.

The Firepower System can parse both NetFlow version 5 and NetFlow version 9 records. NetFlow exporters **must** use one of those versions if you want to export the data to the Firepower System. In addition, the system requires that specific fields be present in the exported NetFlow templates and records. If your NetFlow exporters are using version 9, which you can customize, you **must** make sure that the exported templates and records contain the following fields, in any order:

- IN_BYTES (1)
- IN_PKTS (2)
- PROTOCOL (4)
- TCP_FLAGS (6)
- L4_SRC_PORT (7)
- IPV4_SRC_ADDR (8)
- L4_DST_PORT (11)
- IPV4_DST_ADDR (12)
- LAST_SWITCHED (21)
- FIRST_SWITCHED (22)
- IPV6_SRC_ADDR (27)
- IPV6_DST_ADDR (28)

Because the Firepower System uses managed devices to analyze NetFlow data, your deployment must include at least one managed device that can monitor NetFlow exporters. At least one sensing interface on that managed device must be connected to a network where it can collect the exported NetFlow data. Because the sensing interfaces on managed devices do not usually have IP addresses, the system does not support the direct collection of NetFlow records.

Note that the Sampled NetFlow feature available on some network devices collects NetFlow statistics on only a subset of packets that pass through the devices. Although enabling this feature can improve CPU utilization on the network device, it may affect the NetFlow data you are collecting for analysis by the Firepower System.

Differences between NetFlow and Managed Device Data

Firepower does not directly analyze the traffic represented by NetFlow data. Instead, it converts exported NetFlow records into connection logs and host and application protocol data.

As a result, there are several differences between converted NetFlow data and the discovery and connection data gathered directly by your managed devices. You should keep these differences in mind when performing analysis that requires:

- Statistics on the number of detected connections
- Operating system and other host-related information (including vulnerabilities)
- Application data, including client information, web application information, and vendor and version server information
- Knowing which host in a connection is the initiator and which is the responder

Network Discovery Policy versus Access Control Policy

You configure NetFlow data collection, including connection logging, using rules in the network discovery policy. Contrast this with connection logging for connections detected by Firepower System managed devices, which you configure per access control rule.

Types of Connection Events

Because NetFlow data collection is linked to networks rather than access control rules, you do not have granular control over which NetFlow connections the system logs.

NetFlow data cannot generate Security Intelligence events.

NetFlow-based connection events can be stored in the connection event database only; you cannot send them to the system log or an SNMP trap server.

Number of Connection Events Generated Per Monitored Session

For connections detected directly by managed devices, you can configure the access control rule to log a bidirectional connection event at the beginning or end of a connection, or both.

In contrast, because exported NetFlow records contain unidirectional connection data, the system generates at least two connection events for each NetFlow record it processes. This also means that a summary's connection count is incremented by two for every connection based on NetFlow data, providing an inflated count of the number of connections that are actually occurring on your network.

Because the NetFlow exporter outputs records at a fixed interval even if a connection is still ongoing, long-running sessions can result in multiple exported records, each of which generates a connection event. For example, if the NetFlow exporter exports every five minutes, and a particular connection lasts twelve minutes, the system generates six connection events for that session:

- One pair of events for the first five minutes
- One pair for the second five minutes

- A final pair when the connection is terminated

Host and Operating System Data

Hosts added to the network map from NetFlow data do not have operating system, NetBIOS, or host type (host vs network device) information. You can, however, manually set a host's operating system identity using the host input feature.

Application Data

For connections detected directly by managed devices, the system can identify application protocols, clients, and web applications by examining the packets in the connection.

When the system processes NetFlow records, the system uses a port correlation in `/etc/sf/services` to extrapolate application protocol identity. However, there is no vendor or version information for those application protocols, nor do connection logs contain information on client or web applications used in the session. You can, however, manually provide this information using the host input feature.

Note that a simple port correlation means that application protocols running on non-standard ports may be unidentified or misidentified. Additionally, if no correlation exists, the system marks the application protocol as `unknown` in connection logs.

Vulnerability Mappings

The system cannot map vulnerabilities to hosts monitored by NetFlow exporters, unless you use the host input feature to manually set either a host's operating system identity or an application protocol identity. Note that because there is no client information in NetFlow connections, you cannot associate client vulnerabilities with hosts created from NetFlow data.

Initiator and Responder Information in Connections

For connections detected directly by managed devices, the system can identify which host is the initiator, or source, and which is the responder, or destination. However, NetFlow data does not contain initiator or responder information.

When the Firepower System processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known:

- If both or neither port being used is a well-known port, the system considers the host using the lower-number port to be the responder.
- If only one of the hosts is using a well-known port, the system considers that host to be the responder.

For this purpose, a well-known port is any port that is either numbered from 1 to 1023, or that contains application protocol information in `/etc/sf/services` on the managed device.

In addition, for connections detected directly by managed devices, the system records two byte counts in the corresponding connection event:

- The **Initiator Bytes** field records bytes sent.
- The **Responder Bytes** field records bytes received.

Connection events based on unidirectional NetFlow records contain only one byte count, which the system assigns to either **Initiator Bytes** or **Responder Bytes**, depending on the port-based algorithm. The system

sets the other field to 0. Note that if you are viewing connection summaries (aggregated connection data) of NetFlow records, both fields may be populated.

NetFlow-only Connection Event Fields

A small number of fields are present only in connection events generated from NetFlow records; see Information Available in Connection Event Fields, on page 2389.

Related Topics

Information Available in Connection Event Fields, on page 2389

About User Identity

User identity information can help you to identify the source of policy breaches, attacks, or network vulnerabilities, and trace them to specific users. For example, you could determine:

- Who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level.
- Who initiated an internal attack or portscan.
- Who is attempting unauthorized access to a specified host.
- Who is consuming an unreasonable amount of bandwidth.
- Who has not applied critical operating system updates.
- Who is using instant messaging software or peer-to-peer file-sharing applications in violation of company policy.
- Who is associated with each indication of compromise on your network.

Armed with this information, you can use other features of the Firepower System to mitigate risk, perform access control, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

After you configure user identity sources to gather user data, you can perform user awareness and user control.

Video YouTube videos for configuring identity.

Related Topics

Identity Terminology, on page 1925
Identity Deployments, on page 1930
About User Identity Sources, on page 1926
How to Set Up an Identity Policy, on page 1930

Identity Terminology

This topic discusses common terminology for user identity and user control.

User awareness

Identifying users on your network using *identity sources* (such as user agent or TS Agent). User awareness enables you to identify users from both *authoritative* (such as Active Directory) and *non-authoritative*

(application-based) sources. To use Active Directory as an identity source, you must configure a realm and directory. For more information, see About User Identity Sources, on page 1926.

User control

Configuring an *identity policy* that you associate with an *access control policy*. (The identity policy is then referred to as an access control *subpolicy*.) The identity policy specifies the identity source and, optionally, users and groups belonging to that source.

By associating the identity policy with an access control policy, you determine whether to monitor, trust, block, or allow users or user activity in traffic on your network. For more information, see Access Control Policies, on page 1255.

Authoritative identity sources

A trusted server validated the user login (for example, Active Directory). You can use the data obtained from authoritative logins to perform user awareness and user control. Authoritative user logins are obtained from passive and active authentications:

- *Passive authentications* occur when a user authenticates through an external source. ISE/ISE-PIC, the user agent, and the TS Agent are the passive authentication methods supported by the Firepower System.
- *Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal and Remote Access VPN are the active authentication methods supported by the Firepower System.

Non-authoritative identity sources

An unknown or untrusted server validated the user login. Traffic-based detection is the only non-authoritative identity source supported by the Firepower System. You can use the data obtained from non-authoritative logins to perform user awareness.

About User Identity Sources

The following table provides a brief overview of the user identity sources supported by the Firepower System. Each identity source provides a store of users for user awareness. These users can then be controlled with identity and access control policies.

User Identity Source	Policy	Server Requirements	Type	Authentication Type	User Awareness?	User Control?	For more information, see...
User Agent	Identity	Microsoft Active Directory	Authoritative logins	Passive	Yes	Yes	The User Agent Identity Source, on page 2055
ISE/ISE-PIC	Identity	Microsoft Active Directory	Authoritative logins	Passive	Yes	Yes	The ISE/ISE-PIC Identity Source, on page 2015

User Identity Source	Policy	Server Requirements	Type	Authentication Type	User Awareness?	User Control?	For more information, see...
TS Agent	Identity	Microsoft Windows Terminal Server	Authoritative logins	Passive	Yes	Yes	The Terminal Services (TS) Agent Identity Source, on page 2051
Captive portal	Identity	Microsoft Active Directory	Authoritative logins	Active	Yes	Yes	The Captive Portal Identity Source, on page 2033
Remote Access VPN	Identity	OpenLDAP or Microsoft Active Directory	Authoritative logins	Active	Yes	Yes	The Remote Access VPN Identity Source, on page 2047
	Identity	RADIUS	Authoritative logins	Active	Yes	No	
Traffic-based detection	Network discovery	n/a	Non-authoritative logins	n/a	Yes	No	The Traffic-Based Detection Identity Source, on page 2077

Consider the following when selecting identity sources to deploy:

- You must use traffic-based detection for non-LDAP user logins. For example, if you are using only user agents to detect user activity, restricting non-LDAP logins has no effect.
- You must use traffic-based detection or captive portal to record failed login or authentication activity. A failed login or authentication attempt does not add a new user to the list of users in the database.
- The captive portal identity source requires a managed device with a routed interface. You *cannot* use an inline (also referred to as tap mode) interface with captive portal.

Data from those identity sources is stored in the Firepower Management Center's users database and the user activity database. You can configure Firepower Management Center-server user downloads to automatically and regularly download new user data to your databases.

After you configure identity rules using the desired identity source, you must associate each rule with an access control policy and deploy the policy to managed devices for the policy to have any effect. For more information about access control policies and deployment, see User, Realm, and ISE Attribute Conditions (User Control), on page 412.

For general information about user identity in the Firepower System, see About User Identity, on page 1925.

Video icon YouTube videos for configuring identity sources.

Best Practices for User Identity

We recommend you review the following information before you set up identity policies.

- Know user limits
- Create one realm per AD domain, something about trust
- Health monitor
- Use latest version of ISE/ISE-PIC, two types of remediation
- User agent support drops in 6.7
- Captive portal requires routed interface, several individual tasks
- See TS Agent troubleshooting

Active Directory, LDAP, and realms

The Firepower System supports either Active Directory or LDAP for user awareness and control. The association between an Active Directory or LDAP repository and the FMC is referred to as a *realm*. You should create one realm per LDAP server or Active Directory domain. For details about which versions are supported, see Supported Servers for Realms, on page 1995.

The only user identity source supported by LDAP is captive portal. To use other identity sources (with the exception of ISE/ISE-PIC), you must use Active Directory.

For Active Directory only:

- Create one *directory* per domain controller.

  For details, see Configure a Realm Directory, on page 2006.

Health monitor

The FMC health monitor provides valuable information about the status of various FMC functions, including:

- User/realm mismatches
- Snort memory usage
- ISE connection status

For more information about health modules, see Health Modules, on page 297.

To set up policies to monitor health modules, see Creating Health Policies, on page 304.

Device-specific user limits

Every physical or virtual FMC device has limits to the number of users that can be downloaded. When the user limit is reached, the FMC can run out of memory and can function unreliably as a result.

User limits are discussed in Firepower System User Limit, on page 1935.

If you use the ISE/ISE-PIC identity source, you can optionally limit the subnets the FMC monitors to reduce memory usage using identity mapping filters as discussed in Create an Identity Policy, on page 2066.

Use the latest version of ISE/ISE-PIC

If you expect to use the ISE/ISE-PIC identity source, we strongly recommend you always use the latest version to make sure you get the latest features and bug fixes.

pxGrid 2.0 (which is used by version 2.6 patch 6 or later; or 2.7 patch 2 or later) also changes the remediation used by ISE/ISE-PIC from Endpoint Protection Service (EPS) to Adaptive Network Control (ANC). If you upgrade ISE/ISE-PIC, you must migrate your mediation policies from EPS to ANC.

More information about using ISE/ISE-PIC can be found in ISE/ISE-PIC Guidelines and Limitations, on page 2017.

To set up the ISE/ISE-PIC identity source, see How to Configure ISE/ISE-PIC for User Control, on page 2019.

Captive portal information

Captive portal is the only user identity source for which you can use either LDAP or Active Directory. In addition, your managed devices must be configured to use a routed interface.

Additional guidelines can be found in Captive Portal Guidelines and Limitations, on page 2034.

Setting up captive portal requires performing several independent tasks. For more information, see How to Configure the Captive Portal for User Control, on page 2036.

TS Agent information

The TS Agent user identity source is required to identify user sessions on a Windows Terminal Server. The TS Agent software must be installed on the Terminal Server machine as discussed in the *Cisco Terminal Services (TS) Agent Guide*. In addition, you must synchronize the time on your TS Agent server with the time on the Firepower Management Center.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

For more information, see TS Agent Guidelines, on page 2051.

Associate the identity policy with an access control policy

After you configure your realm, directory, and user identity source, you must set up identity rules in an identity policy. To make the policy effective, you must associate the identity policy with an access control policy.

For more information about creating an identity policy, see Create an Identity Policy, on page 2066.

For more information about creating identity rules, see Create an Identity Rule, on page 2063.

To associate an identity policy with an access control policy, see Associating Other Policies with Access Control, on page 1267.

User agent deprecation and end of support by FMC

End of support is planned for FMC integration with the Cisco Firepower User Agent (hereafter referred to as *user agent*) in a future release.

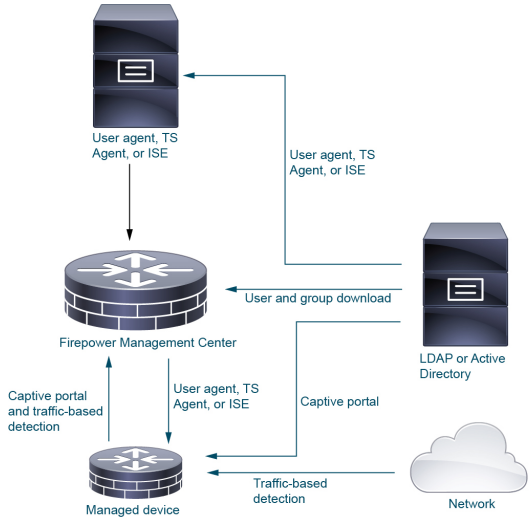
For more information, see End-of-Life and End-of-Support for the Cisco Firepower User Agent.

Identity Deployments

When the system detects user data from a user login, from any identity source, the user from the login is checked against the list of users in the Firepower Management Center user database. If the login user matches an existing user, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The group to which the user belongs is associated with the user as soon as the user is seen by the Firepower Management Center.

The following diagram illustrates how the Firepower System collects and stores user data:



How to Set Up an Identity Policy

This topic provides a high-level overview of setting up an identity policy using any available user identity source: TS Agent, user agent, ISE/ISE-PIC, captive portal, or Remote Access VPN.

Procedure

	Command or Action	Purpose
Step 1	Create a realm.	The *realm* is a trusted user and group store, typically a Microsoft Active Directory repository. The Firepower Management Center downloads users and groups at intervals you specify. You can include or exclude users and groups from being downloaded. See Create a Realm, on page 1997. For details about the options to create a realm, see Realm Fields, on page 1999. **Note** Configuring a realm is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.

	Command or Action	Purpose
Step 2	Create a directory in the realm.	A *directory* is an Active Directory domain controller that organizes information about a computer network's users and network shares. An Active Directory controller provides Directory Services for the realm. Active Directory distributes user and group objects across multiple domain controllers, which are peers that propagate local changes between each other by the use of Directory Services. For more information, see the Active Directory technical specification glossary on MSDN. You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's **Directory** tab page to match user and group credentials for user control. See Configure a Realm Directory, on page 2006.
Step 3	Download users and groups from the realm.	To be able to control users and groups, you must download them to the Firepower Management Center. You can download them to users and groups whenever you want or you can configure the system to download them to them at a specified interval. When you download users and groups, you can specify exceptions; for example, you can exclude the Engineering group from all user control for that realm, or you can exclude the user **`joe.smith`** from user controls that apply to the Engineering group. See Download Users and Groups, on page 2007
Step 4	Enable the realm.	To be able to use the realm for user control, the realm must be enabled. Slide the **State** slider to the right to enable the realm. See Manage a Realm, on page 2008.
Step 5	Create a method to retrieve user and group data (the *identity source*).	Set up an identity source with its unique configuration to be able to control users and groups using data stored in the realm. Identity sources include TS Agent, user agent, captive portal, or Remote VPN. See one of the following: • How to Configure the Captive Portal for User Control, on page 2036 • Configure the User Agent for User Control, on page 2057 • Configure ISE/ISE-PIC for User Control, on page 2026 • Configure RA VPN for User Control, on page 2048
Step 6	Create an identity policy.	An identity policy contains one or more identity rules, optionally organized in categories. See Create an Identity Policy, on page 2066.

	Command or Action	Purpose
		Note Configuring a realm is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.
Step 7	Create one or more identity rules.	Identity rules enable you to specify a number of matching criteria, including the type of authentication, network zones, networks or geolocation, realms, and so on. See Create an Identity Rule, on page 2063.
Step 8	Associate your identity policy with an access control policy.	An access control policy filters and optionally inspects traffic. An identity policy must be associated with an access control policy to have any effect. See Associating Other Policies with Access Control, on page 1267.
Step 9	Deploy the access control policy to at least one managed device.	To use your policy to control user activity, the policy must be deployed to the managed devices to which clients connect. See Deploy Configuration Changes, on page 374.
Step 10	Monitor user activity.	View a list of active sessions collected by user identity sources or a list of user information collected by user identity sources. See Using Workflows, on page 2294. An identity policy is not required if all of the following are true: • You use the ISE/ISE-PIC identity source. • You do not use users or groups in access control policies. • You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions, on page 417.

Configuring Traffic-Based User Detection, on page 2079

The User Activity Database

The user activity database on the Firepower Management Center contains records of user activity on your network detected or reported by all of your configured identity sources. The system logs events in the following circumstances:

- When it detects individual logins or logoffs.
- When it detects a new user.
- When a system administrator manually delete a user.

- When the system detects a user that is not in the database, but cannot add the user because you have reached your user limit.
- When you resolve an indication of compromise associated with a user, or enable or disable indication of compromise rules for a user.

Note If the TS Agent monitors the same users as another passive authentication identity source (such as the user agent or ISE/ISE-PIC), the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firepower Management Center.

You can view user activity detected by the system using the Firepower Management Center web interface. (**Analysis** > **Users** > **User Activity**).

The Users Database

The users database on the Firepower Management Center contains a record for each user detected or reported by all of your configured identity sources. You can use data obtained from an authoritative source for user control.

See About User Identity Sources, on page 1926 for more information about the supported non-authoritative and authoritative identity sources.

The total number of users the Firepower Management Center can store depends on the Firepower Management Center model, as described in Firepower System User Limit, on page 1935. After the user limit is reached, the system prioritizes previously-undetected user data based on its identity source, as follows:

- If the new user is from a non-authoritative identity source, the system does not add the user to the database. To allow new users to be added, you must delete users manually or with a database purge.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new user to the database.

If an identity source is configured to exclude specific user names, user activity data for those user names are not reported to the Firepower Management Center. These excluded user names remain in the database, but are not associated with IP addresses. For more information about the type of data stored by the system, see User Data, on page 2554.

If you have Firepower Management Center high availability configured and the primary fails, no logins reported by a captive portal, user agent, ISE/ISE-PIC, TS Agent, or Remote Access VPN device can be identified during failover downtime, even if the users were previously seen and downloaded to the Firepower Management Center. The unidentified users are logged as Unknown users on the Firepower Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

Note If the TS Agent monitors the same users as another passive authentication identity source (the User Agent or ISE/ISE-PIC), the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firepower Management Center.

When the system detects a new user session, the user session data remains in the users database until one of the following occurs:

- A user on the Firepower Management Center manually deletes the user session.
- An identity source reports the logoff of that user session.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Firepower System Host and User Limits

Your Firepower Management Center model determines how many individual hosts you can monitor with your deployment, as well as how many users you can monitor and use to perform user control.

Related Topics

Purging Data from the FMC Database, on page 218

Firepower System Host Limit

The system adds a host to the network map when it detects activity associated with an IP address in your monitored network (as defined in your network discovery policy). The number of hosts a Firepower Management Center can monitor, and therefore store in the network map, depends on its model.

Table 238: Host Limits by Firepower Management Center Model

FMC Model	Hosts
MC1000	50,000
MC1600	50,000
MC2000	150,000
MC2500	150,000
MC2600	150,000
MC4000	600,000
MC4500	600,000
MC4600	600,000
virtual	50,000

You cannot view contextual data for hosts not in the network map. However, you can perform access control. For example, you can perform application control on traffic to and from a host not in the network map, even though you cannot use a compliance white list to monitor the host's network compliance.

Note The system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

Reaching the Host Limit and Deleting Hosts

The network discovery policy controls what happens when you detect a new host after you reach the host limit; you can drop the new host, or replace the host that has been inactive for the longest time. You can also set the period after which the system removes a host from the network map due to inactivity. Although you can manually delete a host, an entire subnet, or all of your hosts from the network map, if the system detects activity associated with a deleted host, it re-adds the host.

In a multidomain deployment, each leaf domain has its own network discovery policy. Therefore, each leaf domain governs its own behavior when the system discovers a new host.

Domain Properties, on page 365
Network Discovery Data Storage Settings, on page 2085

Firepower System User Limit

Your Firepower Management Center model determines how many individual users you can monitor. The user is added to the Firepower Management Center user database when:

- The user is downloaded from a realm.
- A captive portal or RA-VPN user logs in.
- A user is detected from any identity source (for example, TS Agent).

Only authoritative users are available for user control with access control policies.

Note the following:

The *concurrent user limit* is the number of users logged in to the system at the same time. These users are all *authoritative users*, which means they were reported to the Firepower Management Center by an authoritative user source: User Agent, ISE/ISE-PIC, the TS Agent, and captive portal.

Table 239: Maximum Downloaded Users by Firepower Management Center Model[1]

FMC Model	Maximum Downloaded Users
FMC1000	50,000
FMC1600	50,000
FMC2000	150,000
FMC2500	150,000
FMC2600	150,000
FMC4000	600,000

FMC Model	Maximum Downloaded Users
FMC4500	600,000
FMC4600	600,000
FMCv (any supported hypervisor)	50,000
FMCv 300 (any supported hypervisor)	150,000

[1]—FMC models are subject to end of life and end of sale. For more information, see End-Of-Life and End-Of-Sale Notices.

When the system detects a new, previously-undetected user after the limit has been reached, it prioritizes user data based on their identity source:

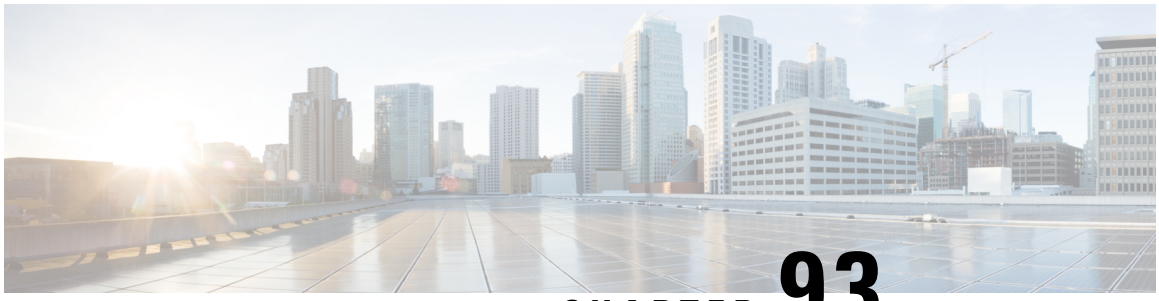
- If the new user is from a non-authoritative source, the system does not add the non-authoritative user to the database. To allow new users to be added, you must delete users manually or purge the database.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period of and adds the new authoritative user to the database.

  If there are only authoritative users, the system deletes the authoritative user who has remained inactive for the longest period of time and adds the new user to the database.

Troubleshooting information can be found in Troubleshoot User Control, on page 415.

Note If your deployment includes an ASA FirePOWER module managed via ASDM, you can store a maximum of 2,000 authoritative users, regardless of your Firepower Management Center model.

Tip Note that if you are using traffic-based detection, you can restrict user logging by protocol to help minimize username clutter and preserve space in the database. For example, you could prevent the system from adding users discovered in AIM, POP3, and IMAP traffic because you know it is traffic from specific contractors or visitors you do not want to monitor.



CHAPTER 93

Host Identity Sources

The following topics provide information on host identity sources:

Overview: Host Data Collection

As the Firepower System passively monitors the traffic that travels through your network, it compares specific packet header values and other unique data from network traffic against established definitions (called *fingerprints*) to determine information about the hosts on your network, including:

- the number and types of hosts (including network devices such as bridges, routers, load balancers, and NAT devices)
- basic network topology data, including the number of hops from the discovery point on the network to the hosts
- the operating systems running on the hosts
- applications on the hosts and users associated with these applications

If the system cannot identify a host's operating system, you can create custom client or server fingerprints. The system uses these fingerprints to identify new hosts. You can map fingerprints to systems in the vulnerability database (VDB) to allow the appropriate vulnerability information to be displayed whenever a host is identified using the custom fingerprint.

Note In addition to collecting host data from monitored network traffic, the system can collect host data from exported NetFlow records, and you can actively add host data using Nmap scans and the host input feature.

Requirements and Prerequisites for Host Identity Sources

Model Support

Any.

Supported Domains

Any, with the exception of custom fingerprinting, which is Leaf only.

User Roles

- Admin
- Discovery Admin, except for third-party data and custom mappings.

Determining Which Host Operating Systems the System Can Detect

To learn which exact operating systems the system can fingerprint, view the list of available fingerprints that is shown during the process of creating a custom OS fingerprint.

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 View the lists of options in the drop-down lists in the **OS Vulnerability Mappings** section. These options are the operating systems that the system can fingerprint.

What to do next

As needed, see Identifying Host Operating Systems, on page 1938.

Identifying Host Operating Systems

If the system does not correctly identify a host's operating system (for example, it shows in the Host Profile as Unknown or is incorrectly identified), try the strategies below.

Try one of the following strategies:

- Check the Network Discovery Identity Conflict Settings.
- Create a custom fingerprint for the host.

- Run an Nmap scan against the host.
- Import data into the network map, using the host input feature.
- Manually enter operating system information.

Custom Fingerprinting

The Firepower System includes operating system *fingerprints* that the system uses to identify the operating system on each host it detects. However, sometimes the system cannot identify a host operating system or misidentifies it because no fingerprints exist that match the operating system. To correct this problem, you can create a *custom fingerprint,* which provides a pattern of operating system characteristics unique to the unknown or misidentified operating system, to supply the name of the operating system for identification purposes.

If the system cannot match a host's operating system, it cannot identify the vulnerabilities for the host, because the system derives the list of vulnerabilities for each host from its operating system fingerprint. For example, if the system detects a host running Microsoft Windows, the system has a stored Microsoft Windows vulnerability list that it adds to the host profile for that host based on the detected Windows operating system.

As an example, if you have several devices on your network running a new beta version of Microsoft Windows, the system cannot identify that operating system or map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for Microsoft Windows, you may want to create a custom fingerprint for one of the hosts to help identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for Microsoft Windows in the fingerprint to associate that list with each host that matches the fingerprint.

When you create a custom fingerprint, the Firepower Management Center lists the set of vulnerabilities associated with that fingerprint for any hosts running the same operating system. If the custom fingerprint you create does not have any vulnerabilities mappings in it, the system uses the fingerprint to assign the custom operating system information you provide in the fingerprint. When the system sees new traffic from a previously detected host, the system updates the host with the new fingerprint information. the system also uses the new fingerprint to identify any new hosts with that operating system the first time they are detected.

Before creating a custom fingerprint, you should determine why the host is not being identified correctly to decide whether custom fingerprinting is a viable solution.

You can create two types of fingerprints with the system:

- Client fingerprints, which identify operating systems based on the SYN packet that the host sends when it connects to a TCP application running on another host on the network.
- Server fingerprints, which identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

Note If both a client and server fingerprint match the same host, the client fingerprint is used.

After creating fingerprints, you must activate them before the system can associate them with hosts.

Related Topics

Creating a Custom Fingerprint for Clients, on page 1942
Creating a Custom Fingerprint for Servers, on page 1944

Managing Fingerprints

After a fingerprint is created and activated, you can edit a fingerprint to make changes or add vulnerability mappings.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**. If the system is awaiting data to create a fingerprint, it automatically refreshes the page every 10 seconds until the fingerprint is created.

Step 3 Manage your custom fingerprints:

- Activate/Deactivate — Activate or deactivate a fingerprint as described in Activating and Deactivating Fingerprints, on page 1940.
- Create — Create fingerprints as described in Creating a Custom Fingerprint for Clients, on page 1942 and Creating a Custom Fingerprint for Servers, on page 1944.
- Edit — Edit a fingerprint as described in Editing an Active Fingerprint, on page 1941 and Editing an Inactive Fingerprint, on page 1941.
- Delete — Click **Delete** ( ) next to the fingerprint you want to delete, and click **OK** to confirm. You can only delete deactivated fingerprints.

Activating and Deactivating Fingerprints

You must activate a custom fingerprint before the system can use it to identify hosts. After the new fingerprint is activated, the system uses it to re-identify previously discovered hosts and discover new hosts.

If you want to stop using a fingerprint, you can deactivate it. Deactivating a fingerprint causes a fingerprint to no longer be used, but allows it to remain on the system. When you deactivate a fingerprint, the operating system is marked as unknown for hosts that use the fingerprint. If the hosts are detected again and match a different active fingerprint, they are then identified by that active fingerprint.

Deleting a fingerprint removes it from the system completely. After deactivating a fingerprint, you can delete it.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**.

Step 3 Click the slider next to the fingerprint you want to activate or deactivate.

Note The activate option is only available if the fingerprint you created is valid. If the slider is not available, try creating the fingerprint again.

Editing an Active Fingerprint

If a fingerprint is *active*, you can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

You can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**

Step 3 Click **Edit** (✎) next to the fingerprint you want to edit.

Step 4 Modify the fingerprint name, description, and custom OS display, if necessary.

Step 5 If you want to delete a vulnerability mapping, click **Delete** next to the mapping in the **Pre-Defined OS Product Maps** section of the page.

Step 6 If you want to add additional operating systems for vulnerability mapping, choose the **Product** and, if applicable, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** and then click **Add OS Definition**.

The vulnerability mapping is added to the **Pre-Defined OS Product Maps** list.

Step 7 Click **Save**.

Editing an Inactive Fingerprint

If a fingerprint is *inactive*, you can modify all elements of the fingerprint and resubmit it to the Firepower Management Center. This includes all properties you specified when creating the fingerprint, such as fingerprint type, target IP addresses and ports, vulnerability mappings, and so on. When you edit an inactive fingerprint and submit it, it is resubmitted to the system and, if it is a client fingerprint, you must resend traffic to the appliance before activating it. Note that you can choose only a single vulnerability mapping for an inactive fingerprint. After you activate the fingerprint, you can map additional operating systems and versions to its vulnerabilities list.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Edit** (✎) next to the fingerprint you want to edit.

Step 4 Make changes to the fingerprint as necessary:

- If you are modifying a client fingerprint, see Creating a Custom Fingerprint for Clients, on page 1942.
- If you are modifying a server fingerprint, see Creating a Custom Fingerprint for Servers, on page 1944.

Step 5 Click **Save**.

What to do next

- If you modified a client fingerprint, remember to send traffic from the host to the appliance gathering the fingerprint.

Creating a Custom Fingerprint for Clients

Client fingerprints identify operating systems based on the SYN packet a host sends when it connects to a TCP application running on another host on the network.

If the Firepower Management Center does not have direct contact with monitored hosts, you can specify a device that is managed by the FMC and is closest to the host you intend to fingerprint when specifying client fingerprint properties.

Before you begin the fingerprinting process, obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the Firepower Management Center or the device you use to obtain the fingerprint. (Cisco strongly recommends that you directly connect the Firepower Management Center or the device to the same subnet that the host is connected to.)
- The network interface (on the Firepower Management Center or the device) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- Access to the host in order to generate client traffic.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 From the **Device** drop-down list, choose the Firepower Management Center or the device that you want to use to collect the fingerprint.

Step 5 Enter a **Fingerprint Name**.

Step 6 Enter a **Fingerprint Description**.

Step 7 From the **Fingerprint Type** list, choose **Client**.

Step 8 In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

Step 9 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 10 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Caution Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 11 If you want to display custom information in the host profile for fingerprinted hosts (or if the host you want to fingerprint does not reside in the **OS Vulnerability Mappings** section), choose **Use Custom OS Display** and provide the values you want to display for the following:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 12 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify **Vendor** and **Product** values in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the **Vendor** and **Product** values.

Note Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the major version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Step 13 Click **Create**.

The status briefly shows `New`, then switches to `Pending`, where it remains until traffic is seen for the fingerprint. Once traffic is seen, it switches to `Ready`.

The Custom Fingerprint status page refreshes every ten seconds until it receives data from the host in question.

Step 14 Using the IP address you specified as the target IP address, access the host you are trying to fingerprint and initiate a TCP connection to the appliance.

To create an accurate fingerprint, traffic **must** be seen by the appliance collecting the fingerprint. If you are connected through a switch, traffic to a system other than the appliance may not be seen by the system.

Example:

Access the web interface of the Firepower Management Center from the host you want to fingerprint or SSH into the FMC from the host. If you are using SSH, use the command below, where localIPv6address is the IPv6 address specified in step 7 that is currently assigned to the host and DCmanagementIPv6address is the management IPv6 address of the FMC. The Custom Fingerprint page should then reload with a "Ready" status.

```
ssh -b localIPv6address DCmanagementIPv6address
```

What to do next

- Activate the fingerprint as described in Activating and Deactivating Fingerprints, on page 1940.

Creating a Custom Fingerprint for Servers

Server fingerprints identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application. Before you begin, you should obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the appliance you use to obtain the fingerprint. Cisco strongly recommends that you directly connect an unused interface on the appliance to the same subnet that the host is connected to.
- The network interface (on the appliance) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- An IP address that is not currently in use and is authorized on the network where the host is located.

Tip If the Firepower Management Center does not have direct contact with monitored hosts, you can specify a managed device that is closest to the host you intend to fingerprint when specifying server fingerprint properties.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 From the **Device** list, choose the Firepower Management Center or the managed device that you want to use to collect the fingerprint.

Step 5 Enter a **Fingerprint Name**.

Step 6 Enter a **Fingerprint Description**.

Step 7 From the **Fingerprint Type** list, choose **Server** to display the server fingerprinting options.

Step 8 In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

Caution You can capture IPv6 fingerprints only with appliances running Version 5.2 and later of the Firepower System.

Step 9 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 10 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Caution Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 11 Click **Get Active Ports**.

Step 12 In the **Server Port** field, enter the port that you want the device chose to collect the fingerprint to initiate contact with, or choose a port from the **Get Active Ports** drop-down list.

You can use any server port that you know is open on the host (for instance, 80 if the host is running a web server).

Step 13 In the **Source IP Address** field, enter an IP address that should be used to attempt to communicate with the host.

You should use a source IP address that is authorized for use on the network but is not currently being used, for example, a DHCP pool address that is currently not in use. This prevents you from temporarily knocking another host offline while you create the fingerprint.

You should exclude that IP address from monitoring in your network discovery policy while you create the fingerprint. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address.

Step 14 In the **Source Subnet Mask** field, enter the subnet mask for the IP address you are using.

Step 15 If the **Source Gateway** field appears, enter the default gateway IP address that should be used to establish a route to the host.

Step 16 If you want to display custom information in the host profile for fingerprinted hosts or if the fingerprint name you want to use does not exist in the OS Definition section, choose **Use Custom OS Display** in the Custom OS Display section.

Provide the values you want to appear in host profiles for the following:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 17 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the vendor and product name.

Note Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Step 18 Click **Create**.
The Custom Fingerprint status page refreshes every ten seconds and should reload with a "Ready" status.

Note If the target system stops responding during the fingerprinting process, the status shows an `ERROR: No Response` message. If you see this message, submit the fingerprint again. Wait three to five minutes (the time period may vary depending on the target system), click **Edit** (✎) to access the Custom Fingerprint page, and then click **Create**.

What to do next

- Activate the fingerprint as described in Activating and Deactivating Fingerprints, on page 1940.

Host Input Data

You can augment the network map by importing network map data from third parties. You can also use the host input feature by modifying operating system or application identities or deleting application protocols, protocols, host attributes, or clients using the web interface.

The system may reconcile data from multiple sources to determine the current identity of an operating system or application.

All data except third-party vulnerabilities is discarded when the affected host is removed from the network map. For more information on setting up scripts or import files, see the *Firepower System Host Input API Guide*.

To include imported data in impact correlations, you must map the data to the operating system and application definitions in the database.

Requirements for Using Third-Party Data

You can import discovery data from third-party systems on your network. However, to enable features where intrusion and discovery data are used together, such as Firepower recommendations, adaptive profile updates,

or impact assessment, you should map as many elements of it as possible to corresponding definitions. Consider the following requirements for using third-party data:

- If you have a third-party system that has specific data on your network assets, you can import that data using the host input feature. However, because third parties may name the products differently, you must map the third-party vendor, product, and versions to the corresponding Cisco product definition. After you map the products, you must enable vulnerability mappings for impact assessment in the Firepower Management Center configuration to allow impact correlation. For versionless or vendorless application protocols, you need to map vulnerabilities for the application protocols in the Firepower Management Center configuration.
- If you import patch information from a third party and you want to mark all vulnerabilities fixed by that patch as invalid, you must map the third-party fix name to a fix definition in the database. All vulnerabilities addressed by the fix will then be removed from hosts where you add that fix.
- If you import operating system and application protocol vulnerabilities from a third party and you want to use them for impact correlation, you must map the third-party vulnerability identification string to vulnerabilities in the database. Note that although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities. After the vulnerabilities are mapped, you must enable third-party vulnerability mappings for impact assessment in the Firepower Management Center configuration. To cause application protocols without vendor or version information to map to vulnerabilities, an administrative user must also map vulnerabilities for the applications in the Firepower Management Center configuration.
- If you import application data and you want to use that data for impact correlation, you must map the vendor string for each application protocol to the corresponding Cisco application protocol definition.

Mapping Third-Party Vulnerabilities, on page 1950
Mapping Vulnerabilities for Servers, on page 1056
Creating Custom Product Mappings, on page 1951

Third-Party Product Mappings

When you add data from third parties to the network map through the user input feature, you must map the vendor, product, and version names used by the third party to the Cisco product definitions. Mapping the products to Cisco definitions assigns vulnerabilities based on those definitions.

Similarly, if you are importing patch information from a third party, such as a patch management product, you must map the name for the fix to the appropriate vendor and product and the corresponding fix in the database.

Mapping Third-Party Products

If you import data from a third party, you must map the Cisco product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Cisco vulnerability information with the third-party product name, which allows the system to perform impact correlation using that data.

If you import data using the host input import feature, you can also use the AddScanResult function to map third-party products to operating system and application vulnerabilities during the import.

For example, if you import data from a third party that lists Apache Tomcat as an application and you know it is version 6 of that product, you could add a third-party map where:

- **Vendor Name** is set to `Apache`.
- **Product Name** is set to `Tomcat`.
- **Apache** is chosen from the **Vendor** drop-down list.
- **Tomcat** is chosen from the **Product** drop-down list.
- **6** is chosen from the **Version** drop-down list

This mapping would cause any vulnerabilities for Apache Tomcat 6 to be assigned to hosts with an application listing for Apache Tomcat.

Note that for versionless or vendorless applications, you must map vulnerabilities for the application types in the Firepower Management Center configuration. Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities.

Tip If you have already created a third-party mapping on another Firepower Management Center, you can export it and then import it onto this FMC. You can then edit the imported mapping to suit your needs.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new map set, click **Create Product Map Set**.
- Edit — To edit an existing map set, click **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- Create — To map a third-party product, click **Add Product Map**.
- Edit — To edit an existing third-party product map, **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the **Vendor String** used by the third-party product.

Step 8 Enter the **Product String** used by the third-party product.

Step 9 Enter the **Version String** used by the third-party product.

Step 10 In the Product Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping from the **Vendor**, **Product**, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** fields.

Example:

If you want a host running a product whose name consists of third-party strings to use the vulnerabilities from Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 11 Click **Save**.

Related Topics

Mapping Vulnerabilities for Servers, on page 1056

Mapping Third-Party Product Fixes

If you map a fix name to a particular set of fixes in the database, you can then import data from a third-party patch management application and apply the fix to a set of hosts. When the fix name is imported to a host, the system marks all vulnerabilities addressed by the fix as invalid for that host.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new map set, click **Create Product Map Set**.
- Edit — To edit an existing map set, click **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- Create — To map a third-party product, click **Add Fix Map.**
- Edit — To edit an existing third-party product map, click **Edit** ( ) next to it. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the name of the fix you want to map in the **Third-Party Fix Name** field.

Step 8 In the **Product Mappings** section, choose the operating system, product, and versions you want to use for fix mapping from the following fields:

- **Vendor**
- **Product**
- **Major Version**
- **Minor Version**
- **Revision Version**
- **Build**
- **Patch**
- **Extension**

Example:

If you want your mapping to assign the fixes from Red Hat Linux 9 to hosts where the patch is applied, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 9 Click **Save** to save the fix map.

Mapping Third-Party Vulnerabilities

To add vulnerability information from a third party to the VDB, you must map the third-party identification string for each imported vulnerability to any existing SVID, Bugtraq, or SID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in the network map and allows impact correlation for those vulnerabilities.

You must enable impact correlation for third-party vulnerabilities to allow correlation to occur. For versionless or vendorless applications, you must also map vulnerabilities for the application types in the Firepower Management Center configuration.

Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot use third-party client vulnerabilities for impact assessment.

Tip If you have already created a third-party mapping on another Firepower Management Center, you can export it and then import it onto this FMC. You can then edit the imported mapping to suit your needs.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new vulnerability set, click **Create Vulnerability Map Set**.
- Edit — To edit an existing vulnerability set, click **Edit** ( ) next to the vulnerability set. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Vulnerability Map**.

Step 5 Enter the third-party identification for the vulnerability in the **Vulnerability ID** field.

Step 6 Enter a **Vulnerability Description**.

Step 7 Optionally:

- Enter a Snort ID in the **Snort Vulnerability ID Mappings** field.
- Enter a legacy vulnerability ID in the **SVID Mappings** field.
- Enter a Bugtraq identification number in the **Bugtraq Vulnerability ID Mappings** field.

Step 8 Click **Add**.

Mapping Vulnerabilities for Servers, on page 1056

Custom Product Mappings

You can use product mappings to ensure that servers input by a third party are associated with the appropriate Cisco definitions. After you define and activate the product mapping, all servers or clients on monitored hosts that have the mapped vendor strings use the custom product mappings. For this reason, you may want to map vulnerabilities for all servers in the network map with a particular vendor string instead of explicitly setting the vendor, product, and version for the server.

Creating Custom Product Mappings

If the system cannot map a server to a vendor and product in the VDB, you can manually create the mapping. When you activate a custom product mapping, the system maps vulnerabilities for the specified vendor and product to all servers in the network map where that vendor string occurs.

Note Custom product mappings apply to all occurrences of an application protocol, regardless of the source of the application data (such as Nmap, the host input feature, or the Firepower System itself). However, if third-party vulnerability mappings for data imported using the host input feature conflicts with the mappings you set through a custom product mapping, the third-party vulnerability mapping overrides the custom product mapping and uses the third-party vulnerability mapping settings when the input occurs.

You create lists of product mappings and then enable or disable use of several mappings at once by activating or deactivating each list. When you specify a vendor to map to, the system updates the list of products to include only those made by that vendor.

After you create a custom product mapping, you must activate the custom product mapping list. After you activate a list of custom product mappings, the system updates all servers with occurrences of the specified vendor strings. For data imported through the host input feature, vulnerabilities update unless you have already explicitly set the product mappings for this server.

If, for example, your company modifies the banner for your Apache Tomcat web servers to read `Internal Web Server`, you can map the vendor string `Internal Web Server` to the vendor **Apache** and the product **Tomcat**, then activate the list containing that mapping, all hosts where a server labeled `Internal Web Server` occurs have the vulnerabilities for Apache Tomcat in the database.

Tip You can use this feature to map vulnerabilities to local intrusion rules by mapping the SID for the rule to another vulnerability.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**

Step 3 Click **Create Custom Product Mapping List**.

Step 4 Enter a **Custom Product Mapping List Name**.

Step 5 Click **Add Vendor String**.

Step 6 In the **Vendor String** field, enter the vendor string that identifies the applications that should map to the chosen vendor and product values.

Step 7 Choose the vendor you want to map to from the **Vendor** drop-down list.

Step 8 Choose the product you want to map to from the **Product** drop-down list.

Step 9 Click **Add** to add the mapped vendor string to the list.

Step 10 Optionally, repeat steps 4 to 8 as needed to add additional vendor string mappings to the list.

Step 11 Click **Save**.

What to do next

- Activate the custom product mapping list. For more information, see Activating and Deactivating Custom Product Mappings, on page 1952.

Editing Custom Product Mapping Lists

You can modify existing custom product mapping lists by adding or removing vendor strings or changing the list name.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click **Edit** () next to the product mapping list you want to edit.

If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make changes to the list as described in Creating Custom Product Mappings, on page 1951.

Step 5 When you finish, click **Save**.

Activating and Deactivating Custom Product Mappings

You can enable or disable use of an entire list of custom product mappings at once. After you activate a custom product mapping list, each mapping on that list applies to all applications with the specified vendor string, whether detected by managed devices or imported through the host input feature.

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click the slider next to the custom product mapping list to activate or deactivate it.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Configuring the Host Input Client

The host input feature allows you to update the Firepower Management Center's network map from a client program running on another appliance. For example, you can add or delete hosts from the network map, or update the host OS and service information. For more information, see *Firepower System Host Input API Guide*.

Before you can run a remote client, you must add the client to the Firepower Management Center’s peers database from the Host Input Client page. You must also copy the authentication certificate generated by the FMC to the client. After completing these steps the client can connect to the FMC.

In a multidomain deployment, you can create a client in any domain. The authentication certificate allows the client to submit network map updates for any leaf domains associated with the client certificate's domain. If

you create a certificate for an ancestor domain (or if your certificate domain later becomes an ancestor domain after adding descendant domains), any clients using that certificate must specify a target leaf domain with every transaction, as described in the *Firepower System Host Input API Guide*.

The Host Input Client shows only clients associated the current domain, so if you want to download or revoke a certificate, switch to the domain where the client was created.

This connection uses TLS 1.2.

Step 1 Choose **System** > **Integration**.

Step 2 Click **Host Input Client**.

Step 3 Click **Create Client**.

Step 4 In the **Hostname** field, enter the host name or IP address of the host running the host input client.

Note If you have not configured DNS resolution, use an IP address.

Step 5 If you want to encrypt the certificate file, enter a password in the **Password** field.

Step 6 Click **Save**.
The host input service allows the host to access port 8307 on the Firepower Management Center and creates an authentication certificate to use during client-server authentication.

Step 7 Click **Download** ( ) next to the certificate file.

Step 8 Save the certificate file to the directory used by your client for SSL/TLS authentication.

Step 9 To revoke access for a client, click **Delete** ( ) next to the host you want to remove.

/firepower/fmc/fmc_config_guide/discovery-host-profiles/t_editing_server_identities.xml

Nmap Scanning

The Firepower System builds network maps through passive analysis of traffic on your network. Information obtained through this passive analysis can occasionally be incomplete, depending on system conditions. However, you can actively scan a host to obtain complete information. For example, if a host has a server running on an open port but the server has not received or sent traffic during the time that the system has been monitoring your network, the system does not add information about that server to the network map. If you directly scan that host using an active scanner, however, you can detect the presence of the server.

The Firepower System integrates with Nmap™, an open source active scanner for network exploration and security auditing.

When you scan a host using Nmap, the system:

- Adds servers on previously undetected open ports to the Servers list in the host profile for that host. The host profile lists any servers detected on filtered or closed TCP ports or on UDP ports in the Scan Results section. By default, Nmap scans more than 1660 TCP ports.

  If the system recognizes a server identified in an Nmap scan and has a corresponding server definition, the system maps the names Nmap uses for servers to the corresponding Cisco server definitions.

- Compares the results of the scan to over 1500 known operating system fingerprints to determine the operating system and assigns scores to each. The operating system assigned to the host is the operating system fingerprint with the highest score.

  The system maps Nmap operating system names to Cisco operating system definitions.

- Assigns vulnerabilities to the host for the added servers and operating systems.

Note:

- A host must exist in the network map before Nmap can append its results to the host profile.
- If the host is deleted from the network map, any Nmap scan results for that host are discarded.

Tip Some scanning options (such as portscans) may place a significant load on networks with low bandwidths. Schedule scans like these to run during periods of low network use.

For more information on the underlying Nmap technology used to scan, refer to the Nmap documentation at http://insecure.org/.

Nmap Remediation Options

You define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used as a response in a correlation policy, run on demand, or scheduled to run at a specific time.

Note that Nmap-supplied server and operating system data remain static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up-to-date.

The following table explains the options configurable in Nmap remediations on a Firepower System.

Table 240: Nmap Remediation Options

Option	Description	Corresponding Nmap Option
Scan Which Address(es) From Event?	When you use an Nmap scan as a response to a correlation rule, select one of the following options to control which address in the event is scanned, that of the source host, the destination host, or both: • **Scan Source and Destination Addresses** scans the hosts represented by the source IP address and the destination IP address in the event. • **Scan Source Address Only** scans the host represented by the event's source IP address. • **Scan Destination Address Only** scans the host represented by the event's destination IP address.	N/A

Option	Description	Corresponding Nmap Option
Scan Types	Select how Nmap scans ports: • The **TCP Syn** scan connects quickly to thousand of ports without using a complete TCP handshake. This options allows you to scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them. If a host acknowledges the Syn packet sent in a TCP Syn scan, Nmap resets the connection. • The **TCP Connect** scan uses the `connect()` system call to open connections through the operating system on the host. You can use the TCP Connect scan if the `admin` user on the Firepower Management Center or managed device does not have raw packet privileges on a host or you are scanning IPv6 networks. In other words, use this option in situations where the TCP Syn scan cannot be used. • The **TCP ACK** scan sends an ACK packet to check whether ports are filtered or unfiltered. • The **TCP Window** scan works in the same way as a TCP ACK scan but can also determine whether a port is open or closed. • The **TCP Maimon** scan identifies BSD-derived systems using a FIN/ACK probe.	**TCP Syn**: `-sS` **TCP Connect**: `-sT` **TCP ACK**: `-sA` **TCP Window**: `-sW` **TCP Maimon**: `-sM`
Scan for UDP ports	Enable to scan UDP ports in addition to TCP ports. Note that scanning UDP ports may be time-consuming, so avoid using this option if you want to scan quickly.	`-sU`

Option	Description	Corresponding Nmap Option
Use Port From Event	If you plan to use the remediation as a response in a correlation policy, enable to cause the remediation to scan only the port specified in the event that triggers the correlation response. • Select **On** to scan the port in the correlation event, rather than the ports you specify during Nmap remediation configuration. If you scan the port in the correlation event, note that the remediation scans the port on the IP addresses that you specify during Nmap remediation configuration. These ports are also added to the remediation's dynamic scan target. • Select **Off** to scan only the ports you specify Nmap remediation configuration. You can also control whether Nmap collects information about operating system and server information. Enable the **Use Port From Event** option to scan the port associated with the new server.	N/A
Scan from reporting detection engine	Enable to scan a host from the appliance where the detection engine that reported the host resides. • To scan from the appliance running the reporting detection engine, select **On**. • To scan from the appliance configured in the remediation, select **Off**.	N/A

Option	Description	Corresponding Nmap Option
Fast Port Scan	Enable to scan only the TCP ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings. Note that you cannot use this option with the **Port Ranges and Scan Order** option. • To scan only the ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings, select **On**. • To scan all TCP ports, select **Off**.	`-F`
Port Ranges and Scan Order	Set the specific ports you want to scan, using Nmap port specification syntax, and the order you want to scan them. Note that you cannot use this option with the **Fast Port Scan** option.	`-p`
Probe open ports for vendor and version information	Enable to detect server vendor and version information. If you probe open ports for server vendor and version information, Nmap obtains server data that it uses to identify servers. It then replaces the Cisco server data for that server. • Select **On** to scan open ports on the host for server information to identify server vendors and versions. • Select **Off** to continue using Cisco server information for the host.	`-sV`
Service Version Intensity	Select the intensity of Nmap probes for service versions. • To use more probes for higher accuracy with a longer scan, select a higher number. • To use fewer probes for less accuracy with a faster scan, select a lower number.	`--version-intensity` <intensity>

Option	Description	Corresponding Nmap Option
Detect Operating System	Enable to detect operating system information for the host. If you configure detection of the operating system for a host, Nmap scans the host and uses the results to create a rating for each operating system that reflects the likelihood that the operating system is running on the host. • Select **On** to scan the host for information to identify the operating system. • Select **Off** to continue using Cisco operating system information for the host.	`-O`
Treat All Hosts As Online	Enable to skip the host discovery process and run a port scan on every host in the target range. Note that when you enable this option, Nmap ignores settings for **Host Discovery Method** and **Host Discovery Port List**. • To skip the host discovery process and run a port scan on every host in the target range, select **On**. • To perform host discovery using the settings for **Host Discovery Method** and **Host Discovery Port List** and skip the port scan on any host that is not available, select **Off**.	`-PN`

Option	Description	Corresponding Nmap Option
Host Discovery Method	Select to perform host discovery for all hosts in the target range, over the ports listed in the **Host Discovery Port Lis**t, or if no ports are listed, over the default ports for that host discovery method. Note that if you also enabled **Treat All Hosts As Online**, however, the **Host Discovery Method** option has no effect and host discovery is not performed. Select the method to be used when Nmap tests to see if a host is present and available: • The **TCP SYN** option sends an empty TCP packet with the SYN flag set and recognizes the host as available if a response is received. TCP SYN scans port 80 by default. Note that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules. • The **TCP ACK** option sends an empty TCP packet with the ACK flag set and recognizes the host as available if a response is received. TCP ACK also scans port 80 by default. Note that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules. • The **UDP** option sends a UDP packet and assumes host availability if a port unreachable response comes back from a closed port. UDP scans port 40125 by default.	**TCP SYN**: `-PS` **TCP ACK**: `-PA` **UDP**: `-PU`
Host Discovery Port List	Specify a customized list of ports, separated by commas, that you want to scan when doing host discovery.	port list for host discovery method

Option	Description	Corresponding Nmap Option
Default NSE Scripts	Enable to run the default set of Nmap scripts for host discovery and server and operating system and vulnerability detection. See https://nmap.org/nsedoc/categories/default.html for the list of default scripts. • To run the default set of Nmap scripts, select **On**. • To skip the default set of Nmap scripts, select **Off**.	`-sC`
Timing Template	Select the timing of the scan process; the higher the number you select, the faster and less comprehensive the scan.	**0**: `T0` (paranoid) **1**: `T1` (sneaky) **2**: `T2` (polite) **3**: `T3` (normal) **4**: `T4` (aggressive) **5**: `T5` (insane)

Nmap Scanning Guidelines

While active scanning can obtain valuable information, overuse of a tool such as Nmap may overload your network resources or even crash important hosts. When using any active scanner, you should create a scanning strategy following these guidelines to make sure that you are scanning only the hosts and ports that you need to scan.

Selecting Appropriate Scan Targets

When you configure Nmap, you can create scan targets that identify which hosts you want to scan. A scan target includes a single IP address, a CIDR block or octet range of IP addresses, an IP address range, or a list of IP addresses or ranges to scan, as well as the ports on the host or hosts.

You can specify targets in the following ways:

- For IPv6 hosts:
  - an exact IP address (for example, `192.168.1.101`)
- For IPv4 hosts:
  - an exact IP address (for example, `192.168.1.101`) or a list of IP addresses separated by commas or spaces
  - an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive).
  - an IP address range using octet range addressing (for example, `192.168.0-255.1-254` scans all addresses in the 192.168.x.x range, except those that end in .0 and or .255)

- an IP address range using hyphenation (for example, `192.168.1.1 - 192.168.1.5` scans the six hosts between 192.168.1.1 and 192.168.1.5, inclusive)
- a list of addresses or ranges separated by commas or spaces (for example, for example, `192.168.1.0/24, 194.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive and the 254 hosts between 194.168.1.1 and 194.168.1.254, inclusive)

Ideal scan targets for Nmap scans include hosts with operating systems that the system is unable to identify, hosts with unidentified servers, or hosts recently detected on your network. Remember that Nmap results cannot be added to the network map for hosts that do not already exist in the network map.

Caution

- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans.
- If a host is deleted from the network map, any Nmap scan results are discarded.
- Make sure you have permission to scan your targets. Using Nmap to scan hosts that do not belong to you or your company may be illegal.

Selecting Appropriate Ports to Scan

For each scan target you configure, you can select the ports you want to scan. You can designate individual port numbers, port ranges, or a series of port numbers and port ranges to identify the exact set of ports that should be scanned on each target.

By default, Nmap scans TCP ports 1 through 1024. If you plan to use the remediation as a response in a correlation policy, you can cause the remediation to scan only the port specified in the event that triggers the correlation response. If you run the remediation on demand or as a scheduled task, or if you do not use the port from the event, you can use other port options to determine which ports are scanned. You can choose to scan only the TCP ports listed in the `nmap-services` file, ignoring other port settings. You can also scan UDP ports in addition to TCP ports. Note that scanning for UDP ports may be time-consuming, so avoid using that option if you want to scan quickly. To select the specific ports or range of ports to scan, use Nmap port specification syntax to identify ports.

Setting Host Discovery Options

You can decide whether to perform host discovery before starting a port scan for a host, or you can assume that all the hosts you plan to scan are online. If you choose not to treat all hosts as online, you can choose what method of host discovery to use and, if needed, customize the list of ports scanned during host discovery. Host discovery does not probe the ports listed for operating system or server information; it uses the response over a particular port only to determine whether a host is active and available. If you perform host discovery and a host is not available, Nmap does not scan ports on that host.

Example: Using Nmap to Resolve Unknown Operating Systems

This example walks through an Nmap configuration designed to resolve unknown operating systems. For a complete look at Nmap configuration, see Managing Nmap Scanning, on page 1965.

If the system cannot determine the operating system on a host on your network, you can use Nmap to actively scan the host. Nmap uses the information it obtains from the scan to rate the possible operating systems. It then uses the operating system that has the highest rating as the host operating system identification.

Using Nmap to challenge new hosts for operating system and server information deactivates the system's monitoring of that data for scanned hosts. If you use Nmap to discover host and server operating system for hosts the system marks as having unknown operating systems, you may be able to identify groups of hosts that are similar. You can then create a custom fingerprint based on one of them to cause the system to associate the fingerprint with the operating system you know is running on the host based on the Nmap scan. Whenever possible, create a custom fingerprint rather than inputting static data through a third-party source like Nmap because the custom fingerprint allows the system to continue to monitor the host operating system and update it as needed.

In this example, you would:

1. Configure a scan instance as described in Adding an Nmap Scan Instance, on page 1965.
2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.
   - Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
   - Enable **Treat All Hosts as Online**, because you know the host exists.
3. Create a correlation rule that triggers when the system detects a host with an unknown operating system. The rule should trigger when **a discovery event occurs** and **the OS information for a host has changed** and it meets the following conditions: **OS Name is unknown**.
4. Create a correlation policy that contains the correlation rule.
5. n the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.
6. Activate the correlation policy.
7. Purge the hosts on the network map to force network discovery to restart and rebuild the network map.
8. After a day or two, search for events generated by the correlation policy. Analyze the Nmap results for the operating systems detected on the hosts to see if there is a particular host configuration on your network that the system does not recognize.
9. If you find hosts with unknown operating systems whose Nmap results are identical, create a custom fingerprint for one of those hosts and use it to identify similar hosts in the future.

Nmap Scan Results, on page 1972
Creating a Custom Fingerprint for Clients, on page 1942
Configuring Correlation Policies, on page 2109

Example: Using Nmap to Respond to New Hosts

This example walks through an Nmap configuration designed to respond to new hosts. For a complete look at Nmap configuration, see Managing Nmap Scanning, on page 1965.

When the system detects a new host in a subnet where intrusions may be likely, you may want to scan that host to make sure you have accurate vulnerability information for it.

You can accomplish this by creating and activating a correlation policy that detects when a new host appears in this subnet, and that launches a remediation that performs an Nmap scan on the host.

To do this, you would:

1. Configure a scan instance as described in Adding an Nmap Scan Instance, on page 1965.
2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.
   - Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
   - Enable **Treat All Hosts as Online**, because you know the host exists.
3. Create a correlation rule that triggers when the system detects a new host on a specific subnet. The rule should trigger when **a discovery event occurs** and **a new host is detected**.
4. Create a correlation policy that contains the correlation rule.
5. In the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.
6. Activate the correlation policy.
7. When you are notified of a new host, check the host profile to see the results of the Nmap scan and address any vulnerabilities that apply to the host.

After you activate the policy, you can periodically check the remediation status view (**Analysis** > **Correlation** > **Status**) to see when the remediation launched. The remediation's dynamic scan target should include the IP addresses of the hosts it scanned as a result of the server detection. Check the host profile for those hosts to see if there are vulnerabilities that need to be addressed for the host, based on the operating system and servers detected by Nmap.

Caution If you have a large or dynamic network, detection of a new host may be too frequent an occurrence to respond to using a scan. To prevent resource overload, avoid using Nmap scans as a response to events that occur frequently. In addition, note that using Nmap to challenge new hosts for operating system and server information deactivates Cisco monitoring of that data for scanned hosts.

Creating an Nmap Remediation, on page 1968
Configuring Correlation Rules, on page 2110
Configuring Correlation Policies, on page 2109

Managing Nmap Scanning

To use Nmap scanning, you must, at minimum, configure an Nmap scan instance and an Nmap remediation. Configuring an Nmap scan target is optional.

Step 1 Configure the Nmap scan:

- Add an Nmap scan instance as described in Adding an Nmap Scan Instance, on page 1965.
- Create an Nmap remediation as described in Creating an Nmap Remediation, on page 1968.
- Optionally, add an Nmap scan target as described in Adding an Nmap Scan Target, on page 1967.

Step 2 Run the Nmap scan:

- Run an on-demand Nmap scan as described in Running an On-Demand Nmap Scan, on page 1971.
- Configure automatic Nmap scans as described in Nmap Scan Automation, on page 203.
- Schedule automatic Nmap scans as described in Scheduling an Nmap Scan, on page 203.

What to do next

- Monitor the Nmap scan in progress by viewing the related task; see Viewing Task Messages, on page 344.
- Optionally, refine the scan:
  - Edit an Nmap scan instance as described in Editing an Nmap Scan Instance, on page 1966.
  - Edit an Nmap scan target as described in Editing an Nmap Scan Target, on page 1968.
  - Edit an Nmap remediation as described in Editing an Nmap Remediation, on page 1970.

Adding an Nmap Scan Instance

You can set up a separate scan instance for each Nmap module that you want to use to scan your network for vulnerabilities. You can set up scan instances for the local Nmap module on the Firepower Management Center and for any devices you want to use to run scans remotely. The results of each scan are always stored on the Firepower Management Center where you configure the scan, even if you run the scan from a remote device. To prevent accidental or malicious scanning of mission-critical hosts, you can create a blacklist for the instance to indicate the hosts that should never be scanned with the instance.

You cannot add a scan instance with the same name as any existing scan instance.

In a multidomain deployment, the system displays scan instances created in the current domain, which you can edit. It also displays scan instances created in ancestor domains, which you cannot edit. To view and edit scan instances in a lower domain, switch to that domain.

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Add the remediation:

- If you accessed the list via the first method above, locate the Add a New Instance section, choose the Nmap Remediation module from the drop-down list, and click **Add**.
- If you accessed the list via the second method above, click **Add Nmap Instance**.

Step 3 Enter an **Instance Name**.

Step 4 Enter a **Description**.

Step 5 Optionally, in the **Blacklisted Scan hosts** field, specify any hosts or networks that should *never* be scanned with this scan instance, using the following syntax:

- For IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
- For IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between `192.168.1.1` and `192.168.1.254`, inclusive)
- Note that you cannot use an exclamation mark (!) to negate an address value.

Note If you specifically target a scan to a host that is in a blacklisted network, that scan will not run.

Step 6 Optionally, to run the scan from a remote device instead of the Firepower Management Center, specify the IP address or name of the device as it appears in the Information page for the device in the FMC web interface, in the **Remote Device Name** field.

Step 7 Click **Create**.
When the system is done creating the instance, it displays it in edit mode.

Step 8 Optionally, add an Nmap remediation to the instance. To do so, locate the Configured Remediations section of the instance, click **Add**, and create a remediation as described in Creating an Nmap Remediation, on page 1968.

Step 9 Click **Cancel** to return to the list of instances.

Note If you accessed the list of Nmap scan instances via the **Scanners** option, the system does not display the instance you added unless you also added a remediation to the instance. To view any instances to which you have not yet added remedations, use the **Instances** menu option to access the list.

Editing an Nmap Scan Instance

When you edit a scan instance, you can view, add, and delete remediations associated with the instance. Delete an Nmap scan instance when you no longer want to use the Nmap module profiled in the instance. Note that when you delete the scan instance, you also delete any remediations that use that instance.

In a multidomain deployment, the system displays scan instances created in the current domain, which you can edit. It also displays scan instances created in ancestor domains, which you cannot edit. To view and edit scan instances in a lower domain, switch to that domain.

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Click **View** ( ) next to the instance you want to edit.

Step 3 Make changes to the scan instance settings as described in Adding an Nmap Scan Instance, on page 1965.

Step 4 Click **Save**.

Step 5 Click **Done**.

What to do next

- Optionally, add a new remediation to the scan instance; see Creating an Nmap Remediation, on page 1968
- Optionally, edit a remediation associated with the instance; see Editing an Nmap Remediation, on page 1970.
- Optionally, delete a remediation associated with the instance; see Running an On-Demand Nmap Scan, on page 1971.
- Optionally, delete the scan instance by clicking **Delete** ( ) next to it.

Adding an Nmap Scan Target

When you configure an Nmap module, you can create and save scan targets that identify the hosts and ports you want to target when you perform an on-demand or a scheduled scan, so that you do not have to construct a new scan target every time. A scan target includes a single IP address or a block of IP addresses to scan, as well as the ports on the host or hosts. For Nmap targets, you can also use Nmap octet range addressing or IP address ranges. For more information on Nmap octet range addressing, refer to the Nmap documentation at http://insecure.org.

Note:

- Scans for scan targets containing a large number of hosts can take an extended period of time. As a workaround, scan fewer hosts at a time.
- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.
- In a multidomain deployment, the system displays scan targets created in the current domain, which you can edit. It also displays scan targets created in ancestor domains, which you cannot edit. To view and edit scan targets in a lower domain, switch to that domain.

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Create Scan Target**.

Step 4 In the **Name** field, enter the name you want to use for this scan target.

Step 5 In the **IP Range** text box, specify the host or hosts you want to scan using the syntax described in Nmap Scanning Guidelines, on page 1961.

Note If you use a comma in a list of IP addresses or ranges in a scan target, the comma converts to a space when you save the target.

Step 6 In the **Ports** field, specify the ports you want to scan.

You can enter any of the following, using values from 1 to 65535:

- a port number
- a list of ports separated by commas
- a range of port numbers separated by a dash
- ranges of port numbers separated by dashes, separated by commas

Step 7 Click **Save**.

Related Topics

Nmap Scan Automation, on page 203

Editing an Nmap Scan Target

Tip You might want to edit a remediation's dynamic scan target if you do not want to use the remediation to scan a specific IP address, but the IP address was added to the target because the host was involved in a correlation policy violation that launched the remediation.

Delete a scan target if you no longer want to scan the hosts listed in it.

In a multidomain deployment, the system displays scan targets created in the current domain, which you can edit. It also displays scan targets created in ancestor domains, which you cannot edit. To view and edit scan targets in a lower domain, switch to that domain.

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Edit** () next to the scan target you want to edit.

If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make modifications as necessary. For more information, see Adding an Nmap Scan Target, on page 1967.

Step 5 Click **Save**.

Step 6 Optionally, delete the scan target by clicking **Delete** () next to it.

Creating an Nmap Remediation

An Nmap remediation can only be created by adding it to an existing Nmap scan instance. The remediation defines the settings for the scan. It can be used as a response in a correlation policy, run on demand, or run as a scheduled task at a specific time.

Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

For general information about Nmap functionality, refer to the Nmap documentation at http://insecure.org.

In a multidomain deployment, the system displays Nmap remediations created in the current domain, which you can edit. It also displays Nmap remediations created in ancestor domains, which you cannot edit. To view and edit Nmap remediations in a lower domain, switch to that domain.

Before you begin

- Add an Nmap scan instance as described in Adding an Nmap Scan Instance, on page 1965.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Click **View** ( ) next to the instance to which you want to add the remediation.

Step 3 In the Configured Remediations section, click **Add**.

Step 4 Enter a **Remediation Name**.

Step 5 Enter a **Description**.

Step 6 If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, a connection event, or a user event, configure the **Scan Which Address(es) From Event?** option.

Tip If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or a host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

Note Do **not** assign an Nmap remediation as a response to a correlation rule that triggers on a traffic profile change.

Step 7 Configure the **Scan Type** option.

Step 8 Optionally, to scan UDP ports in addition to TCP ports, choose **On** for the **Scan for UDP ports** option.

Tip A UDP portscan takes more time than a TCP portscan. To speed up your scans, leave this option disabled.

Step 9 If you plan to use this remediation in response to correlation policy violations, configure the **Use Port From Event** option.

Step 10 If you plan to use this remediation in response to correlation policy violations and want to run the scan using the appliance running the detection engine that detected the event, configure the **Scan from reporting detection engine** option.

Step 11 Configure the **Fast Port Scan** option.

Step 12 In the **Port Ranges and Scan Order** field, enter the ports you want to scan by default, using Nmap port specification syntax, in the order you want to scan those ports.

Use the following format:

- Specify values from 1 to 65535.
- Separate ports using commas or spaces.
- Use a hyphen to indicate a port range.
- When scanning for both TCP and UDP ports, preface the list of TCP ports you want to scan with a T and the list of UDP ports with a U.

Note The **Use Port From Event** option overrides this setting when the remediation is launched in response to a correlation policy violation, as described in step 8.

Example:

To scan ports 53 and 111 for UDP traffic, then scan ports 21-25 for TCP traffic, enter `U:53,111,T:21-25`.

Step 13 To probe open ports for server vendor and version information, configure **Probe open ports for vendor and version information**.

Step 14 If you choose to probe open ports, set the number of probes used by choosing a number from the **Service Version Intensity** drop-down list.

Step 15 To scan for operating system information, configure **Detect Operating System** settings.

Step 16 To determine whether host discovery occurs and whether port scans are only run against available hosts, configure **Treat All Hosts As Online**.

Step 17 To set the method you want Nmap to use when it tests for host availability, choose a method from the **Host Discovery Method** drop-down list.

Step 18 If you want to scan a custom list of ports during host discovery, enter a list of ports appropriate for the host discovery method you chose, separated by commas, in the **Host Discovery Port List** field.

Step 19 Configure the **Default NSE Scripts** option to control whether to use the default set of Nmap scripts for host discovery and server, operating system, and vulnerability discovery.

Tip See http://nmap.org/nsedoc/categories/default.html for the list of default scripts.

Step 20 To set the timing of the scan process, choose a timing template number from the **Timing Template** drop-down list.

Choose a higher number for a faster, less comprehensive scan and a lower number for a slower, more comprehensive scan.

Step 21 Click **Create**.
When the system is done creating the remediation, it displays it in edit mode.

Step 22 Click **Done** to return to the related instance.

Step 23 Click **Cancel** to return to the instance list.

Related Topics

Nmap Scan Automation, on page 203
Nmap Remediation Options, on page 1954

Editing an Nmap Remediation

Modifications you make to Nmap remediations do not affect scans in progress. The new settings take effect when the next scan starts. Delete an Nmap remediation if you no longer need it.

In a multidomain deployment, the system displays Nmap remediations created in the current domain, which you can edit. It also displays Nmap remediations created in ancestor domains, which you cannot edit. To view and edit Nmap remediations in a lower domain, switch to that domain.

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Access the remediation you want to edit:

- If you accessed the list via the first method above, click **View** ( ) next to the relevant instance, and then click it again next to the remediation you want to edit in the Configured Remediations section.
- If you accessed the list via the second method above, click **View** ( ) next to the remediation you want to edit.

Step 3 Make modifications as necessary as described in Creating an Nmap Remediation, on page 1968.

Step 4 Click **Save** if you want to save your changes, or **Done** if you want to exit without saving.

Step 5 Optionally, delete the remediation by clicking **Delete** ( ) next to it.

Running an On-Demand Nmap Scan

You can launch on-demand Nmap scans whenever needed. You can specify the target for an on-demand scan by entering the IP addresses and ports you want to scan or by choosing an existing scan target.

Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

Before you begin

- Optionally, add an Nmap scan target; see Adding an Nmap Scan Target, on page 1967.

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 Next to the Nmap remediation you want to use to perform the scan, click **Scan** ( ).

Step 3 Optionally, to scan using a saved scan target, choose a target from the **Saved Targets** drop-down list, and click **Load**.

Step 4 In the **IP Range(s)** field, specify the IP address for hosts you want to scan or modify the loaded list.

Note:

- For hosts with IPv4 addresses, you can specify multiple IP addresses separated by commas or use CIDR notation. You can also negate IP addresses by preceding them with an exclamation point (!).
- For hosts with IPv6 addresses, use an exact IP address. Ranges are not supported.

Step 5 In the **Ports** field, specify the ports you want to scan or modify the loaded list.

You can enter a port number, a list of ports separated by commas, or a range of port numbers separated by a dash.

Step 6 In a multidomain deployment, use the **Domain** field to specify the leaf domain where you want to perform the scan.

Step 7 Click **Scan Now**.

What to do next

- Optionally, monitor the task status; see Viewing Task Messages, on page 344.

Related Topics

Nmap Scan Automation, on page 203

Firepower System IP Address Conventions, on page 17
Ports in Searches, on page 2327

Nmap Scan Results

You can monitor Nmap scans in progress, import results from scans previously performed through the Firepower System or results preformed outside the Firepower System, and view and analyze scan results.

You can view scan results that you create using the local Nmap module as a rendered page in a pop-up window. You can also download the Nmap results file in raw XML format.

You can also view operating system and server information detected by Nmap in host profiles and in the network map. If a scan of a host produces server information for servers on filtered or closed ports, or if a scan collects information that cannot be included in the operating system information or the servers section, the host profile includes those results in an Nmap Scan Results section.

Viewing Nmap Scan Results

When an Nmap scan is complete, you can view a table of scan results.

You can manipulate the results view depending on the information you are looking for. The page you see when you access scan results differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of scan results. You can also create a custom workflow that displays only the information that matches your specific needs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

You can download and view the Nmap results using the Nmap Version 1.01 DTD, available at http://insecure.org.

You can also clear scan results.

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Scan Results**.

Step 3 You have the following choices:

- Adjust the time range as described in Event Time Constraints, on page 2310.
- To use a different workflow, including a custom workflow, click **(switch workflows)** by the workflow title.
- To view the scan results as a rendered page in a pop-up window, click **View** next to the scan job.
- To save a copy of the scan results file so that you can view the raw XML code in any text editor, click **Download** next to the scan job.
- To sort scan results, click the column title. Click the column title again to reverse the sort order.
- To constrain the columns that appear, click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

  Tip To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, Click the expand arrow to expand the search constraints, then click the column name under **Disabled Columns**.

- To drill down to the next page in the workflow, see Using Drill-Down Pages, on page 2301.

- To configure scan instances and remediations, click **Scanners** in the toolbar and see Managing Nmap Scanning, on page 1965.
- To navigate within and between workflow pages, see Workflow Page Navigation Tools, on page 2299.
- To navigate to other event views to view associated events, choose the name of the event view you want to see from the **Jump to** drop-down list.
- To search for scan results, enter your search criteria in the appropriate fields.

Related Topics

Nmap Scan Results Fields, on page 1973

Nmap Scan Results Fields

When you run an Nmap scan, the Firepower Management Center collects the scan results in a database. The following table describes the fields in the scan results table that can be viewed and searched.

Table 241: Scan Results Fields

Field	Description
Start Time	The date and time that the scan that produced the results started.
End Time	The date and time that the scan that produced the results ended.
Target	The IP address (or host name, if DNS resolution is enabled) of the scan target for the scan that produced the results.
Scan Type	Either `Nmap` or the name of the third-party scanner to indicate the type of the scan that produced the results.
Scan Mode	The mode of the scan that produced the results: • `On Demand` — results from scans run on demand. • `Imported` — results from scans on a different system and imported onto the Firepower Management Center. • `Scheduled` — results from scans run as a scheduled task.
Results	The results of the scan.
Domain	The domain of the scan target. This field is only present in a multidomain deployment.

Related Topics

Event Searches, on page 2323

Importing Nmap Scan Results

You can import XML results files created by an Nmap scan performed outside of the Firepower System. You can also import XML results files that you previously downloaded from the Firepower System. To import Nmap scan results, the results file must be in XML format and adhere to the Nmap Version 1.01 DTD. For

more information on creating Nmap results and on the Nmap DTD, refer to the Nmap documentation at http://insecure.org.

A host must already exist in the network map before Nmap can append its results to the host profile.

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Import Results**.

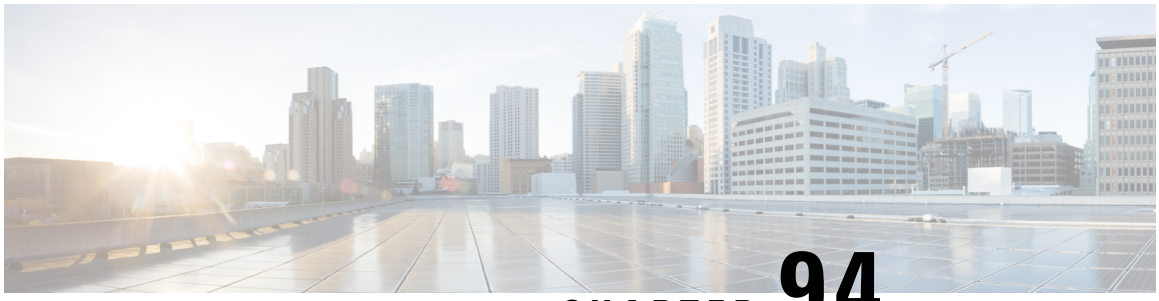
Step 3 In a multidomain deployment, choose a leaf domain from the **Domain** drop-down list to specify where you want to store the imported results.

Step 4 Click **Browse** to navigate to the results file.

Step 5 After you return to the Import Results page, click **Import** to import the results.

History for Host Identity Sources

Feature	Version	Details
Security improvement to the host input data feature	6.5	TLS 1.2 is now used for communication between your FMC and the host input client. The topic Configuring the Host Input Client, on page 1952has been updated with this information.



CHAPTER 94

Application Detection

The following topics describe Firepower System application detection :

Overview: Application Detection

When the Firepower System analyzes IP traffic, it attempts to identify the commonly used applications on your network. Application awareness is crucial to application control.

There are three types of applications that the system detects:

- *application protocols* such as HTTP and SSH, which represent communications between hosts
- *clients* such as web browsers and email clients, which represent software running on the host
- *web applications* such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic

The system identifies applications in your network traffic according to the characteristics specified in the detector. For example, the system can identify an application by an ASCII pattern in the packet header. In addition, Secure Socket Layers (SSL) protocol detectors use information from the secured session to identify the application from the session.

There are two sources of application detectors in the Firepower System:

- *System-provided detectors* detect web applications, clients, and application protocols.

  The availability of system-provided detectors for applications (and operating systems) depends on the version of the Firepower System and the version of the VDB you have installed. Release notes and

advisories contain information on new and updated detectors. You can also import individual detectors authored by Professional Services.

- *Custom application protocol detectors* are user-created and detect web applications, clients, and application protocols.

You can also detect application protocols through *implied application protocol detection*, which infers the existence of an application protocol based on the detection of a client.

The system identifies only those application protocols running on hosts in your monitored networks, as defined in the network discovery policy. For example, if an internal host accesses an FTP server on a remote site that you are not monitoring, the system does not identify the application protocol as FTP. On the other hand, if a remote or internal host accesses an FTP server on a host you are monitoring, the system can positively identify the application protocol.

If the system can identify the client used by a monitored host to connect to a non-monitored server, the system identifies the client's corresponding application protocol, but does not add the protocol to the network map. Note that client sessions must include a response from the server for application detection to occur.

The system characterizes each application that it detects; see Application Characteristics, on page 406. The system uses these characteristics to create groups of applications, called *application filters*. Application filters are used to perform access control and to constrain search results and data used in reports and dashboard widgets.

You can also supplement application detector data using exported NetFlow records, Nmap active scans, and the host input feature.

Related Topics

Best Practices for Configuring Application Control, on page 409
Application Detector Fundamentals, on page 1976

Application Detector Fundamentals

The Firepower System uses *application detectors* to identify the commonly used applications on your network. Use the Detectors page (**Policies** > **Application Detectors**) to view the detector list and customize detection capability.

Whether you can modify a detector or change its state (active or inactive) depends on its type. The system uses only active detectors to analyze application traffic.

Note Cisco-provided detectors may change with Firepower System and VDB updates. See the release notes and advisories for information on updated detectors.

Cisco-Provided Internal Detectors

Internal detectors are a special category of detectors for client, web application, and application protocol traffic. Internal detectors are delivered with system updates and are always on.

If an application matches against internal detectors designed to detect client-related activity and no specific client detector exists, a generic client may be reported.

Cisco-Provided Client Detectors

Client detectors detect client traffic and are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate client detectors. You can export a client detector only if you import it.

Cisco-Provided Web Application Detectors

Web application detectors detect web applications in HTTP traffic payloads and are delivered via VDB or system update. Web application detectors are always on.

Cisco-Provided Application Protocol (Port) Detectors

Port-based application protocol detectors use well-known ports to identify network traffic. They are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate application protocol detectors, and view a detector definition to use it as the basis for a custom detector.

Cisco-Provided Application Protocol (Firepower) Detectors

Firepower-based application protocol detectors analyze network traffic using Firepower application fingerprints and are delivered via VDB or system update. You can activate and deactivate application protocol detectors.

Custom Application Detectors

Custom application detectors are pattern-based. They detect patterns in packets from client, web application, or application protocol traffic. You have full control over imported and custom detectors.

Identification of Application Protocols in the Web Interface

The following table outlines how the Firepower System identifies detected application protocols:

Table 242: Firepower System Identification of Application Protocols

Identification	Description
application protocol name	The Firepower Management Center identifies an application protocol with its name if the application protocol was: • positively identified by the system • identified using NetFlow data and there is a port-application protocol correlation in `/etc/sf/services` • manually identified using the host input feature • identified by Nmap or another active source

Identification	Description
`pending`	The Firepower Management Center identifies an application protocol as `pending` if the system can neither positively nor negatively identify the application. Most often, the system needs to collect and analyze more connection data before it can identify a pending application. In the Application Details and Servers tables and in the host profile, the `pending` status appears only for application protocols where specific application protocol traffic was detected (rather than inferred from detected client or web application traffic).
`unknown`	The Firepower Management Center identifies an application protocol as `unknown` if: • the application does not match any of the system's detectors • the application protocol was identified using NetFlow data, but there is no port-application protocol correlation in `/etc/sf/services`
blank	All available detected data has been examined, but no application protocol was identified. In the Application Details and Servers tables and in the host profile, the application protocol is left blank for non-HTTP generic client traffic with no detected application protocol.

Implied Application Protocol Detection from Client Detection

If the system can identify the client used by a monitored host to access a non-monitored server, the Firepower Management Center infers that the connection is using the application protocol that corresponds with the client. (Because the system tracks applications only on monitored networks, connection logs usually do not include application protocol information for connections where a monitored host is accessing a non-monitored server.)

This process, or *implied application protocol detection*, has the following consequences:

- Because the system does not generate a New TCP Port or New UDP Port event for these servers, the server does not appear in the Servers table. In addition, you cannot trigger either discovery event alerts or correlation rules using the detection of these application protocol as a criterion.
- Because the application protocol is not associated with a host, you cannot view its details in host profiles, set its server identity, or use its information in host profile qualifications for traffic profiles or correlation rules. In addition, the system does not associate vulnerabilities with hosts based on this type of detection.

You can, however, trigger correlation events on whether the application protocol information is present in a connection. You can also use the application protocol information in connection logs to create connection trackers and traffic profiles.

Host Limits and Discovery Event Logging

When the system detects a client, server, or web application, it generates a discovery event unless the associated host has already reached its maximum number of clients, servers, or web applications.

Host profiles display up to 16 clients, 100 servers, and 100 web applications per host.

Note that actions dependent on the detection of clients, servers, or web applications are unaffected by this limit. For example, access control rules configured to trigger on a server will still log connection events.

Special Considerations for Application Detection

SFTP

In order to detect SFTP traffic, the same rule must also detect SSH.

Squid

The system positively identifies Squid server traffic when either:

- the system detects a connection from a host on your monitored network to a Squid server where proxy authentication is enabled, or
- the system detects a connection from a Squid proxy server on your monitored network to a target system (that is, the destination server where the client is requesting information or another resource).

However, the system cannot identify Squid service traffic if:

- a host on your monitored network connects to a Squid server where proxy authentication is disabled, or
- the Squid proxy server is configured to strip Via: header fields from its HTTP responses

SSL Application Detection

The system provides application detectors that can use session information from a Secure Socket Layers (SSL) session to identify the application protocol, client application, or web application in the session.

When the system detects an encrypted connection, it marks that connection as either a generic HTTPS connection or as a more specific secure protocol, such as SMTPS, when applicable. When the system detects an SSL session, it adds `SSL client` to the **Client** field in connection events for the session. If it identifies a web application for the session, the system generates discovery events for the traffic.

For SSL application traffic, managed devices can also detect the common name from the server certificate and match that against a client or web application from an SSL host pattern. When the system identifies a specific client, it replaces `SSL client` with the name of the client.

Because the SSL application traffic is encrypted, the system can use only information in the certificate for identification, not application data within the encrypted stream. For this reason, SSL host patterns can sometimes only identify the company that authored the application, so SSL applications produced by the same company may have the same identification.

In some instances, such as when an HTTPS session is launched from within an HTTP session, managed devices detect the server name from the client certificate in a client-side packet.

To enable SSL application identification, you must create access control rules that monitor responder traffic. Those rules must have either an application condition for the SSL application or URL conditions using the

URL from the SSL certificate. For network discovery, the responder IP address does not have to be in the networks to monitor in the network discovery policy; the access control policy configuration determines whether the traffic is identified. To identify detections for SSL applications, you can filter by the `SSL protocol` tag, in the application detectors list or when adding application conditions in access control rules.

Referred Web Applications

Web servers sometimes refer traffic to other websites, which are often advertisement servers. To help you better understand the context for referred traffic occurring on your network, the system lists the web application that referred the traffic in the **Web Application** field in events for the referred session. The VDB contains a list of known referred sites. When the system detects traffic from one of those sites, the referring site is stored with the event for that traffic. For example, if an advertisement accessed via Facebook is actually hosted on Advertising.com, the detected Advertising.com traffic is associated with the Facebook web application. The system can also detect referring URLs in HTTP traffic, such as when a website provides a simple link to another site; in this case, the referring URL appears in the HTTP Referrer event field.

In events, if a referring application exists, it is listed as the web application for the traffic, while the URL is that for the referred site. In the example above, the web application for the connection event for that traffic would be Facebook, but the URL would be Advertising.com. A referred application may appear as the web application if no referring web application is detected, if the host refers to itself, or if there is a chain of referrals. In the dashboard, connection and byte counts for web applications include sessions where the web application is associated with traffic referred by that application.

Note that if you create a rule to act specifically on referred traffic, you should add a condition for the referred application, rather than the referring application. To block Advertising.com traffic referred from Facebook, for example, add an application condition to your access control rule for the Advertising.com application.

Custom Application Detectors

If you use a custom application on your network, you can create a custom web application, client, or application protocol detector that provides the system with the information it needs to identify the application. The type of application detector is determined by your selections in the **Protocol**, **Type**, and **Direction** fields.

Client sessions must include a responder packet from the server for the system to begin detecting and identifying application protocols in server traffic. Note that, for UDP traffic, the system designates the source of the responder packet as the server.

If you have already created a detector on another Firepower Management Center, you can export it and then import it onto this Firepower Management Center. You can then edit the imported detector to suit your needs. You can export and import custom detectors as well as detectors provided by Cisco Professional Services. However, you **cannot** export or import any other type of Cisco-provided detectors.

Custom Application Detector and User-Defined Application Fields

You can use the following fields to configure custom application detectors and user-defined applications.

Custom Application Detector Fields: General

Use the following fields to configure basic and advanced custom application detectors.

Application Protocol

The application protocol you want to detect. This can be a system-provided application or a user-defined application.

If you want the application to be available for exemption from active authentication (configured in your identity rules), you must select or create an application protocol with the **`User-Agent Exclusion`** tag.

Description

A description for the application detector.

Name

A name for the application detector.

Detector Type

The type of detector, **`Basic`** or **`Advanced`**. Basic application detectors are created in the web interface as a series of fields. Advanced application detectors are created externally and uploaded as custom .lua files.

Custom Application Detector Fields: Detection Patterns

Use the following fields to configure the detection patterns for basic custom application detectors.

Direction

The source of the traffic the detector should inspect, **`Client`** or **`Server`**.

Offset

The location in a packet, in bytes from the beginning of the packet payload, where the system should begin searching for the pattern.

Because packet payloads start at byte 0, calculate the offset by subtracting 1 from the number of bytes you want to move forward from the beginning of the packet payload. For example, to look for the pattern in the fifth bit of the packet, type `4` in the **Offset** field.

Pattern

The pattern string associated with the **Type** you selected.

Ports

The port of the traffic the detector should inspect.

Protocol

The protocol you want to detect. Your protocol selection determines whether the **Type** or the **URL** field displays.

The protocol (and, in some cases, your subsequent selections in the **Type** and **Direction** fields) determine the type of application detector you create: web application, client, or application protocol.

Detector Type	Protocol	Type or Direction
Web Application	HTTP	**Type** is **`Content Type`** or **`URL`**
	RTMP	Any
	SSL	Any
Client	HTTP	**Type** is **`User Agent`**
	SIP	Any
	TCP or UDP	**Direction** is **`Client`**
Application Protocol	TCP or UDP	**Direction** is **`Server`**

Type

The type of pattern string you entered. The options you see are determined by the **Protocol** you selected. If you selected **`RTMP`** as the protocol, the **URL** field displays instead of the **Type** field.

Note If you select **`User Agent`** as the **Type**, the system automatically sets the **Tag** for the application to **`User-Agent Exclusion`**.

Type Selection	String Characteristics
`Ascii`	The string is ASCII encoded.
`Common Name`	The string is the value in the commonName field within the server response message.
`Content Type`	The string is the value in the content-type field within the server response header.
`Hex`	The string is in hexadecimal notation.
`Organizational Unit`	The string is the value in the organizationName field within the server response message.
`SIP Server`	The string is the value in the From field within the message header.
`SSL Host`	The string is the value in the server_name field within the ClientHello message.

Type Selection	String Characteristics
URL	The string is a URL. **Note** The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.
User Agent	The string is the value in the user-agent field within the GET request header. It is also available for the SIP protocol and indicates that the string is the value in the User-Agent field within the SIP message header.

URL

Either a full URL or a section of a URL from the swfURL field within the C2 message of a RTMP packet. This field displays instead of the **Type** field when you select **RTMP** as the **Protocol**.

Note The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.

User-Defined Application Fields

Use the following fields to configure user-defined applications within basic and advanced custom application detectors.

Business Relevance

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

Categories

A general classification for the application that describes its most essential function.

Description

A description for the application.

Name

A name for the application.

Risk

The likelihood that the application is used for purposes that might be against your organization's security policy: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

Tags

One or more predefined tags that provide additional information about the application. If you want an application to be available for exemption from active authentication (configured in your identity rules), you must add the **`User-Agent Exclusion`** tag to your application.

Configuring Custom Application Detectors

You can configure basic or advanced custom application detectors.

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Create Custom Detector**.

Step 3 Enter a **Name** and a **Description**.

Step 4 Select an **Application Protocol**. You have the following options:

- If you are creating a detector for an existing application protocol (for example, if you want to detect a particular application protocol on a non-standard port), select the application protocol from the drop-down list.
- If you are creating a detector for a user-defined application, follow the procedure outlined in Creating a User-Defined Application, on page 1985.

Step 5 Select a **Detector Type**.

Step 6 Click **OK**.

Step 7 Configure **Detection Patterns** or **Detection Criteria**:

- If you are configuring a basic detector, specify preset **Detection Patterns** as described in Specifying Detection Patterns in Basic Detectors, on page 1985.
- If you are configuring an advanced detector, specify custom **Detection Criteria** as described in Specifying Detection Criteria in Advanced Detectors, on page 1986.

Caution Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.

Step 8 Optionally, use **Packet Captures** to test the new detector as described in Testing a Custom Application Protocol Detector, on page 1987.

Step 9 Click **Save**.

Note If you include the application in an access control rule, the detector is automatically activated and cannot be deactivated while in use.

What to do next

- Activate the detector as described in Activating and Deactivating Detectors, on page 1990.

Related Topics

Custom Application Detector and User-Defined Application Fields, on page 1981

Creating a User-Defined Application

Applications, categories, and tags created here are available in access control rules and in the application filter object manager as well.

Caution Creating a user-defined application immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984.

Step 1 On the Create Detector page, click **Add**.

Step 2 Type a **Name**.

Step 3 Type a **Description**.

Step 4 Select a **Business Relevance**.

Step 5 Select a **Risk**.

Step 6 Click **Add** next to Categories to add a category and type a new category name, or select an existing category from the **Categories** drop-down list.

Step 7 Optionally, click **Add** next to Tags to add a tag and type a new tag name, or select an existing tag from the **Tags** drop-down list.

Step 8 Click **OK**.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Custom Application Detector and User-Defined Application Fields, on page 1981

Specifying Detection Patterns in Basic Detectors

You can configure a custom application protocol detector to search application protocol packet headers for a particular pattern string. You can also configure detectors to search for multiple patterns; in that case the application protocol traffic must match all of the patterns for the detector to positively identify the application protocol.

Application protocol detectors can search for ASCII or hexadecimal patterns, using any offset.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984.

Step 1 On the Create Detector page, in the Detection Patterns section, click **Add**.

Step 2 Select a **Protocol** for traffic the detector should inspect.

Step 3 Specify the pattern **Type** you want to detect.

Step 4 Type a **Pattern String** that matches the **Type** you specified.

Step 5 Optionally, type the **Offset** (in bytes).

Step 6 Optionally, to identify application protocol traffic based on the port it uses, type a port from 1 to 65535 in the **Port(s)** field. To use multiple ports, separate them by commas.

Step 7 Optionally, select a **Direction**: `Client` or `Server`.

Step 8 Click **OK**.

Tip If you want to delete a pattern, click **Delete** ( ) next to the pattern you want to delete.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specifying Detection Criteria in Advanced Detectors, on page 1986

Specifying Detection Criteria in Advanced Detectors

Caution Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.

Caution Do not upload .lua files from untrusted sources.

Custom .lua files contain your custom application detector settings. Creating custom .lua files requires advanced knowledge of the lua programming language and experience with Cisco's C-lua API. Cisco strongly recommends you use the following to prepare .lua files:

- third-party instruction and reference material for the lua programming language
- The Open Source Detectors Developers Guide: https://www.snort.org/downloads
- OpenAppID Snort community resources: http://blog.snort.org/search/label/openappid

Note The system does not support .lua files that reference system calls or file I/O.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984.
- Prepare to create a valid .lua file by downloading and studying the .lua files for comparable detectors. For more information about downloading detector files, see Viewing or Downloading Detector Details, on page 1988.
- Create a valid .lua file that contains your custom application detector settings.

Step 1 On the Create Detector page for an advanced custom application detector, in the Detection Criteria section, click **Add**.

Step 2 Click **Browse...** to navigate to the `.lua` file and upload it.

Step 3 Click **OK**.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specifying Detection Patterns in Basic Detectors, on page 1985

Testing a Custom Application Protocol Detector

If you have a packet capture (pcap) file that contains packets with traffic from the application protocol you want to detect, you can test a custom application protocol detector against that pcap file. Cisco recommends using a simple, clean pcap file without unnecessary traffic.

Pcap files must be 256 KB or smaller; if you try to test your detector against a larger pcap file, the Firepower Management Center automatically truncates it and tests the incomplete file. You must fix the unresolved checksums in a pcap before using the file to test a detector.

Before you begin

- Configure your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984.

Step 1 On the Create Detector page, in the Packet Captures section, click **Add**.

Step 2 Browse to the pcap file in the pop-up window and click **OK**.

Step 3 To test your detector against the contents of the pcap file, click evaluate next to the pcap file. A message indicates whether the test succeeded.

Step 4 Optionally, repeat steps 1 to 3 to test the detector against additional pcap files.

Tip To delete a pcap file, click **Delete** ( ) next to the file you want to delete.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 1984. You must save and activate the detector before the system can use it to analyze traffic.

Viewing or Downloading Detector Details

You can use the detectors list to view application detector details (all detectors) and download detector details (custom application detectors only).

Step 1 To view application detector details, do one of the following:

- See the *Cisco Firepower Application Detector Reference* for the relevant VDB version at https://www.cisco.com/c/en/us/support/security/defense-center/products-technical-reference-list.html
- a. Select **Policies** > **Application Detectors**.

  b. Filter the list to find a particular detector.

  c. Click **Information** ( )

Step 2 To download detector details for a custom application detector, click **Download** ( ).

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have the necessary permissions.

Sorting the Detector List

By default, the Detectors page lists detectors alphabetically by name. An up or down arrow next to a column heading indicates that the page is sorted by that column in that direction.

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the appropriate column heading.

Filtering the Detector List

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Expand one of the filter groups described in Filter Groups for the Detector List, on page 1989 and select the check box next to a filter. To select all filters in a group, right-click the group name and select **Check All**.

Step 3 If you want to remove a filter, click **Remove** ( ) in the name of the filter in the **Filters** field or disable the filter in the filter list. To remove all filters in a group, right-click the group name and select **Uncheck All**.

Step 4 If you want to remove all filters, click **Clear all** next to the list of filters applied to the detectors.

Filter Groups for the Detector List

You can use several filter groups, separately or in combination, to filter the list of detectors.

Name

Finds detectors with names or descriptions containing the string you type. Strings can contain any alphanumeric or special character.

Custom Filter

Finds detectors matching a custom application filter created on the object management page.

Author

Finds detectors according to who created the detector. You can filter detectors by:

- any individual user who has created or imported a custom detector
- Cisco, which represents all Cisco-provided detectors *except* individually imported add-on detectors (you are the author for any detector that you import)
- **Any User**, which represents all detectors not provided by Cisco

State

Finds detectors according to their state, that is, **Active** or **Inactive**.

Type

Finds detectors according to the detector type, as described in Application Detector Fundamentals, on page 1976.

Protocol

Finds detectors according to which traffic protocol the detector inspects.

Category

Finds detectors according to the categories assigned to the application they detect.

Tag

Finds detectors according to the tags assigned to the application they detect.

Risk

Finds detectors according to the risks assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Business Relevance

Finds detectors according to the business relevance assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Navigating to Other Detector Pages

Step 1 Select **Policies** > **Application Detectors**.

Step 2 If you want to view the next page, click **Right Arrow** ( ).

Step 3 If you want to view the previous page, click **Left Arrow** ( ).

Step 4 If you want to view a different page, type the page number and press Enter.

Step 5 If you want to jump to the last page, click **Right End Arrow** ( ).

Step 6 If you want to jump to the first page, click **Left End Arrow** ( ).

Activating and Deactivating Detectors

You must activate a detector before you can use it to analyze network traffic. By default, all Cisco-provided detectors are activated.

You can activate multiple application detectors for each port to supplement the system's detection capability.

When you include an application in an access control rule in a policy and that policy is deployed, if there is no active detector for that application, one or more detectors automatically activate. Similarly, while an application is in use in a deployed policy, you cannot deactivate a detector if deactivating leaves no active detectors for that application.

Tip For improved performance, deactivate any application protocol, client, or web application detectors you do not intend to use.

Caution Activating or deactivating a system or custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the slider next to the detector you want to activate or deactivate. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Note Some application detectors are required by other detectors. If you deactivate one of these detectors, a warning appears to indicate that the detectors that depend on it are also disabled.

Editing Custom Application Detectors

Use the following procedure to modify custom application detectors.

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Edit** ( ) next to the detector you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Make changes to the detector as described in Configuring Custom Application Detectors, on page 1984.

Step 4 You have the following saving options, depending on the state of the detector:

- To save an inactive detector, click **Save**.
- To save an inactive detector as a new, inactive detector, click **Save as New**.
- To save an active detector and immediately start using it, click **Save and Reactivate**.

  Caution Saving and reactivating a custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

- To save an active detector as a new, inactive detector, click **Save as New**.

Deleting Detectors

You can delete custom detectors as well as individually imported add-on detectors provided by Cisco Professional Services. You cannot delete any of the other Cisco-provided detectors, though you can deactivate many of them.

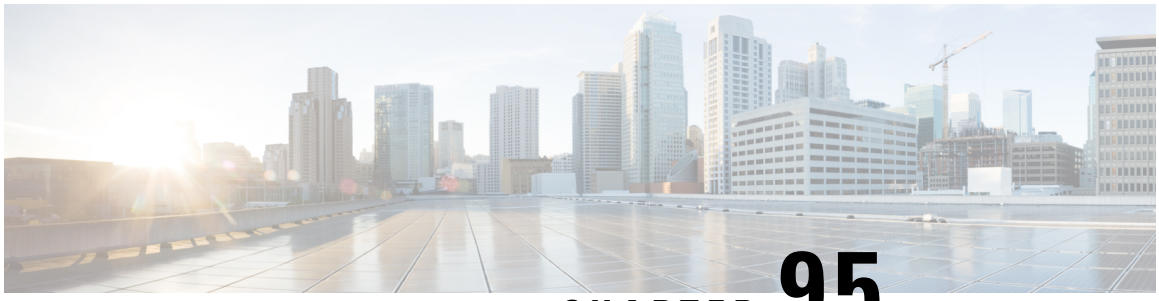
Note While a detector is in use in a deployed policy, you cannot delete the detector.

Caution Deleting an activated custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Delete** ( ) next to the detector you want to delete. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **OK**.



CHAPTER 95

Create and Manage Realms

The following topics discuss how to create and manage *realms*, which are user stores for user awareness and control:

About Realms

Realms are connections between the Firepower Management Center and the user accounts on the servers you monitor. They specify the connection settings and authentication filter settings for the server. Realms can:

- Specify the users and user groups whose activity you want to monitor.
- Query the user repository for user metadata on authoritative users, as well as some non-authoritative users: POP3 and IMAP users detected by traffic-based detection and users detected by traffic-based detection, a user agent, a TS Agent, or ISE/ISE-PIC.

You can add multiple domain controllers as directories in a realm, but they must share the same basic realm information. The directories in a realm must be exclusively LDAP or exclusively Active Directory (AD) servers. After you enable a realm, your saved changes take effect next time the Firepower Management Center queries the server.

To perform user awareness, you must configure a realm for any of the Supported Servers for Realms. The system uses these connections to query the servers for data associated with POP3 and IMAP users, and to collect data about LDAP users discovered through traffic-based detection.

The system uses the email addresses in POP3 and IMAP logins to correlate with LDAP users on an Active Directory, or OpenLDAP. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the system associates the LDAP user's metadata with that user.

To perform user control, you can configure any of the following:

- A realm for an AD server or for either the user agent or ISE/ISE-PIC

Note Configuring a realm is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.

- A realm for an AD server for the TS Agent
- For captive portal, an LDAP realm.

  A realm sequence is not supported for LDAP.

About User Download

You can configure a realm to establish a connection between the Firepower Management Center and an LDAP or AD server to retrieve user and user group metadata for certain detected users:

- LDAP and AD users authenticated by captive portal or reported by ISE/ISE-PIC or a user agent. This metadata can be used for user awareness and user control.
- POP3 and IMAP user logins detected by traffic-based detection, if those users have the same email address as an LDAP or AD user. This metadata can be used for user awareness.

You configure LDAP server or Active Directory domain controller connections as a directory in a realm. You must check **Download users and user groups for access control** to download a realm's user and user group data for user awareness and user control.

The Firepower Management Center obtains the following information and metadata about each user:

- LDAP user name
- First and last names
- Email address
- Department
- Telephone number

About User Activity Data

User activity data is stored in the user activity database and user identity data is stored in the users database. The maximum number of users you can store and use in access control depends on your Firepower Management Center model. When choosing which users and groups to include, make sure the total number of users is less than your model limit. If your access control parameters are too broad, the Firepower Management Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the Tasks tab page of the Message Center.

Note If you remove a user that has been detected by the system from your user repository, the Firepower Management Center does *not* remove that user from its users database; you must manually delete it. However, your LDAP changes *are* reflected in access control rules when the Firepower Management Center next updates its list of authoritative users.

Video YouTube video on creating a realm.

Realms and Trusted Domains

When you configure a *realm* in the Firepower Management Center, it is associated with an Active Directory or LDAP *domain*.

A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.

The Firepower System and trusted domains

The Firepower System does not support trusted AD domains. This means that the Firepower System does not track which configured domains trust each other, and does not know which domains are parent or child domains of each other. The Firepower System also has not been tested to assure support for environments that use cross-domain trust, even when the trust relationship is exercised outside of the Firepower System.

Supported Servers for Realms

You can configure realms to connect to the following types of servers, providing they have TCP/IP access from the Firepower Management Center:

Server Type	Supported for User Agent data retrieval?	Supported for ISE/ISE-PIC data retrieval?	Supported for TS Agent data retrieval?	Supported for captive portal data retrieval?
Microsoft Active Directory on Windows Server 2008 and Windows Server 2012	No User agent supported on Windows Server 2008 and 2012 only	Yes	Yes	Yes
OpenLDAP on Linux	No	No	No	Yes

Note If the TS Agent is installed on a Microsoft Active Directory Windows Server shared with another passive authentication identity source (the User Agent or ISE/ISE-PIC), the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firepower Management Center.

Note the following about your server group configurations:

- To perform user control on user groups or on users in groups, you must configure user groups on the LDAP or Active Directory server.
- Group names cannot start with `s-` because it is used internally by LDAP.

Neither group names or nor organizational unit names can contain special characters like asterisk (*), equals (=), or backslash (\); otherwise, users in those groups or organizational units are not downloaded and are not available for identity policies.

- To configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft recommends that Active Directory has no more than 5000 users per group in Windows Server 2008 or 2012. For more information, see Active Directory Maximum Limits—Scalability on MSDN.

  If necessary, you can modify your Active Directory server configuration to increase this default limit and accommodate more users.

- To uniquely identify the users reported by a server in your Remote Desktop Services environment, you must configure the Cisco Terminal Services (TS) Agent. When installed and configured, the TS Agent assigns unique ports to individual users so the Firepower System can uniquely identify those users. (Microsoft changed the name *Terminal Services* to *Remote Desktop Services*.)

  For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Supported Server Object Class and Attribute Names

The servers in your realms *must* use the attribute names listed in the following table for the Firepower Management Center to retrieve user metadata from the servers. If the attribute names are incorrect on your server, the Firepower Management Center cannot populate its database with the information in that attribute.

Table 243: Map of attribute names to Firepower Management Center fields

Metadata	FMC Attribute	LDAP ObjectClass	Active Directory Attribute	OpenLDAP Attribute
LDAP user name	Username	• user • inetOrgPerson	samaccountname	cn uid
first name	First Name		givenname	givenname
last name	Last Name		sn	sn
email address	Email		mail userprincipalname (if mail has no value)	mail
department	Department		department distinguishedname (if department has no value)	ou
telephone number	Phone		telephonenumber	telephonenumber

Note The LDAP ObjectClass for groups is `group`, `groupOfNames`, (`group-of-names` for Active Directory) or `groupOfUniqueNames`.

For more information about ObjectClasses and attributes, see the following references:

- Microsoft Active Directory:
  - ObjectClasses: All Classes on MSDN
  - Attributes: All Attributes on MSDN
- OpenLDAP: RFC 4512

Create a Realm

The following procedure enables you to create a *realm* (a connection between the FMC and an Active Directory forest) and a *directory* (a connection between the FMC and an LDAP server or an Active Directory domain controller).

(Recommended.) To connect securely from the FMC to your Active Directory server, first perform the following tasks:

- Export the Active Directory Server's Root Certificate, on page 2004
- Find the Active Directory Server's Name, on page 2004

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

For more information about realm and directory configuration fields, see Realm Fields, on page 1999 and Realm Directory and Download fields, on page 2002.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration**.

Step 3 Click **Realms**.

Step 4 To create a new realm, click **Add Realm**.

Step 5 To perform other tasks (such as enable, disable, or delete a realm), see Manage a Realm, on page 2008.

Step 6 Enter realm information as discussed in Realm Fields, on page 1999.

Step 7 (Optional.) Click **Test AD Join** to test the connection to the realm.

Note For a Microsoft Active Directory realm test to succeed, you must enter values in both the **AD Join Username** and **AD Join Password** fields and the user must have sufficient privileges to add computers to the domain. For more information, see Realm Fields, on page 1999.

Step 8 Click **OK**.

Step 9 Configure at least one directory as discussed in Configure a Realm Directory, on page 2006.

Step 10 Configure user and user group download (required for access control) as discussed in Download Users and Groups, on page 2007.

Step 11 Click **Realm Configuration**.

Step 12 Enter user session timeout values, in minutes, for **User Agent and ISE/ISE-PIC Users**, **TS Agent Users**, **Captive Portal Users**, **Failed Captive Portal Users**, and **Guest Captive Portal Users**.

Step 13 When you're finished configuring the realm, click **Save**.

What to do next

- Configure a Realm Directory, on page 2006
- Edit, delete, enable, or disable a realm; see Manage a Realm, on page 2008.
- Compare Realms, on page 2008.

- Optionally, monitor the task status; see Viewing Task Messages, on page 344.

Realm Fields

The following fields are used to configure a realm.

Realm Configuration Fields

These settings apply to all Active Directory servers or domain controllers (also referred to as *directories*) in a realm.

Name

A unique name for the realm.

- To use the realm in identity policies, the system supports alphanumeric and special characters.
- To use the realm in RA VPN configurations, the system supports alphanumeric, hyphen (-), underscore (_), and plus (+) characters.

Description

(Optional.) Enter a description of the realm.

Type

The type of realm, **AD** for Microsoft Active Directory or **LDAP** for other supported LDAP repositories. For a list of supported LDAP repositories, see Supported Servers for Realms, on page 1995. You can authenticate captive portal users with an LDAP repository; all others require Active Directory.

Note Only captive portal supports an LDAP realm.

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

AD Join Username and AD Join Password

For Microsoft Active Directory realms intended for Kerberos captive portal active authentication, the distinguished username and password of any Active Directory user with appropriate rights to create a Domain Computer account in the Active Directory domain.

Keep the following in mind:

- DNS must be able to resolve the domain name to an Active Directory domain controller's IP address.
- The user you specify must be able to join computers to the Active Directory domain.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

If you choose **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Protocol** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

Directory Username and Directory Password

The distinguished username and password for a user with appropriate access to the user information you want to retrieve.

Note the following:

- For Microsoft Active Directory, the user does not need elevated privileges. You can specify any user in the domain.
- For OpenLDAP, the user's access privileges are determined by the `<level>` parameter discussed in section 8 of the OpenLDAP specification. The user's `<level>` should be `auth` or better.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

Base DN

The directory tree on the server where the Firepower Management Center should begin searching for user data.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of **`ou=security,dc=example,dc=com`**.

Group DN

The directory tree on the server where the Firepower Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported Server Object Class and Attribute Names, on page 1996.

Note Following is the list of characters the Firepower System *supports* in users, groups, DNs in your directory server. Using any characters other than the following could result in the Firepower System failing to download users and groups.

Entity	Supported characters
User name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Group name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Base DN and Group DN	**a-z A-Z 0-9 ! @ $ % ^ & * ( ) _ - . ~ ` [ ]**

Group Attribute

(Optional.) The group attribute for the server, **`Member`** or **`Unique Member`**.

The following fields are available when you edit an existing realm.

User Session Timeout

Enter the number of minutes before user sessions time out. The default is 1440 (24 hours) after the user's login event. After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Firepower Management Center as Unknown (except for **Failed Captive Portal Users**).

You can set timeout values for the following:

- **User Agent and ISE/ISE-PIC Users**: Timeout for users tracked by the user agent or by ISE/ISE-PIC, which are types of passive authentication.

  The timeout value you specify does *not* apply to pxGrid SXP session topic subscriptions (for example, destination SGT mappings). Instead, session topic mappings are preserved as long as there is no delete or update message for a given mapping from ISE.

  For more information about ISE/ISE-PIC, see The ISE/ISE-PIC Identity Source, on page 2015.

- **TS Agent Users**: Timeout for users tracked by the TS Agent, which is a type of passive authentication. For more information, see The Terminal Services (TS) Agent Identity Source, on page 2051.

- **Captive Portal Users**: Timeout for users who successfully log in using the captive portal, which is a type of active authentication. For more information, see The Captive Portal Identity Source, on page 2033.

- **Failed Captive Portal Users**: Timeout for users who do not successfully log in using the captive portal. You can configure the **Maximum login attempts** before the user is seen by the Firepower Management Center as Failed Auth User. A Failed Auth User can optionally be granted access to the network using access control policy and, if so, this timeout value applies to those users.

  For more information about failed captive portal logins, see Captive Portal Fields, on page 2043.

- **Guest Captive Portal Users**: Timeout for users who log in to the captive portal as a guest user. For more information, see The Captive Portal Identity Source, on page 2033.

Realm Directory and Download fields

Realm Directory Fields

These settings apply to individual servers (such as Active Directory domain controllers) in a realm.

Hostname / IP Address

Fully qualified host name of the Active Directory domain controller machine. To find the fully qualified name, see Find the Active Directory Server's Name, on page 2004.

Port

The port to use for the Firepower Management Center-controller connection.

Encryption

(Strongly recommended.) The encryption method to use for the Firepower Management Center-server connection:

- **`STARTTLS`**—encrypted LDAP connection
- **`LDAPS`**—encrypted LDAP connection
- **`None`**—unencrypted LDAP connection (unsecured traffic)

To communicate securely with an Active Directory server, see Connect Securely to Active Directory, on page 2003.

SSL Certificate

The SSL certificate to use for authentication to the server. You must configure **`STARTTLS`** or **`LDAPS`** as the **Encryption** type in order to use an SSL certificate.

If you are using a certificate to authenticate, the name of the server in the certificate must match the server **Hostname / IP Address**. For example, if you use 10.10.10.250 as the IP address but **`computer1.example.com`** in the certificate, the connection fails.

User Download Fields

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Download users and groups (required for user access control)

Enables you to download users and groups for user awareness and user control.

Begin automatic download at, Repeat every

Specifies the frequency of the automatic downloads.

Download Now

Click to synchronize groups and users with AD.

Available Groups, Add to Include, Add to Exclude

Limits the groups that can be used in policy.

- Groups that are displayed in the **Available Groups** field are available for policy unless you move groups to the **Add to Include** or **Add to Exclude** field.
- If you move groups to the **Add to Include** field, only those groups are downloaded and user data is available for user awareness and user control.
- If you move groups to the **Add to Exclude** field, all groups *except* these are downloaded and available for user awareness and user control.
- To include users from groups that are not included, enter the user name in the field below **Groups to Include** and click **Add**.
- To exclude users from groups that are not excluded, enter the user name in the field below **Groups to Exclude** and click **Add**.

Note The users that are downloaded to the Firepower Management Center is calculated using the formula **R = I - (E+e) + i**, where

- R is list of downloaded users
- I is included groups
- E is excluded groups
- e is excluded users
- i is included users

Begin automatic download at

Enter the time and time interval at which to download users and groups from AD.

Connect Securely to Active Directory

To create a secure connection between an Active Directory server and the FMC (which we strongly recommend), you must perform all of the following tasks:

- Export the Active Directory server's root certificate.
- Import the root certificate into the FMC as a trusted CA certificate.
- Find the Active Directory server's fully qualified name.
- Create the realm directory.

See one of the following tasks for more information.

Related Topics

Export the Active Directory Server's Root Certificate, on page 2004
Find the Active Directory Server's Name, on page 2004
Configure a Realm Directory, on page 2006

Find the Active Directory Server's Name

To configure a realm directory in the FMC, you must know the fully qualified server name, which you can find as discussed in the procedure that follows.

Before you begin

You must log in to the Active Directory server as a user with sufficient privileges to view the computer's name.

Step 1 Log in to the Active Directory server.
Step 2 Click **Start**.
Step 3 Right-click **This PC**.
Step 4 Click **Properties**.
Step 5 Click **Advanced System Settings**.
Step 6 Click the **Computer Name** tab.
Step 7 Note the value of **Full computer name**.
You must enter this exact name when you configure the realm directory in the FMC.

What to do next

Create a realm directory.

Related Topics

Export the Active Directory Server's Root Certificate, on page 2004

Export the Active Directory Server's Root Certificate

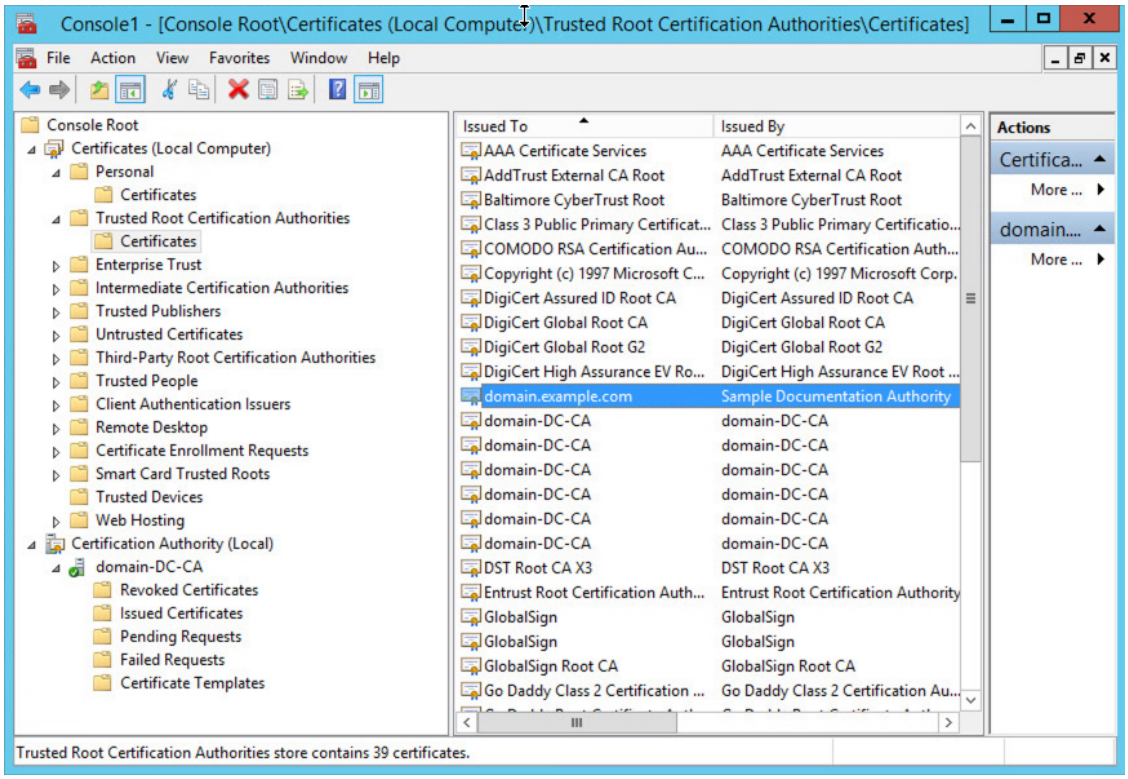
The task that follows discusses how to export the Active Directory server's root certificate, which is required to connect securely to the FMC to obtain user identity information.

Before you begin

You must know the name of your Active Directory server's root certificate. The root certificate might have the same name as the domain or the certificate might have a different name. The procedure that follows shows one way you can find the name; there could be other ways, however.

Step 1 Following is one way to find the name of the Active Directory Server's root certificate; consult Microsoft documentation for more information:
a) Log in to the Active Directory server as a user with privileges to run the Microsoft Management Console.
b) Click **Start** and enter **mmc**.
c) Click **File** > **Add/Remove Snap-in**

d) From the Available Snap-ins list in the left pane, click **Certificates (local)**.
e) Click **Add**.
f) At the Certificates snap-in dialog box, click **Computer Account** and click **Next**.
g) At the Select Computer dialog box, click **Local Computer** and click **Finish**.
h) *Windows Server 2012 only*. Repeat the preceding steps to add the Certification Authority snap-in.
i) Click **Console Root** > **Trusted Certification Authorities** > **Certificates**.
The server's trusted certificates are displayed in the right pane. The following figure is only an example for Windows Server 2012; yours will probably look different.



Step 2 Export the certificate using the **certutil** command.

This is only one way to export the certificate. It's a convenient way to export the certificate, especially if you can run a web browser and connect to the FMC from the Active Directory server.

a) Click **Start** and enter **cmd**.
b) Enter the command **certutil -ca.cert** *certificate-name*.
The server's certificate is displayed on the screen.
c) Copy the entire certificate to the clipboard, starting with **-----BEGIN CERTIFICATE-----** and ending with **-----END CERTIFICATE-----** (including those strings).

What to do next

Import the Active Directory server's certificate into the FMC as a Trusted CA Certificate as discussed in Adding a Trusted CA Object, on page 482.

Related Topics

Find the Active Directory Server's Name, on page 2004

Configure a Realm Directory

This procedure enables you to create a realm directory, which corresponds to an LDAP server or a Microsoft Active Directory domain controller. An Active Directory server can have multiple domain controllers, each of which is capable of authenticating different users and groups.

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

If you have not done so already, we recommend you start using TLS/SSL encryption to authenticate with an Active Directory server.

For more information about realm directory configuration fields, see Realm Fields, on page 1999.

Before you begin

(Recommended.) To connect securely from the FMC to your Active Directory server, first perform the following tasks:

- Export the Active Directory Server's Root Certificate, on page 2004
- Find the Active Directory Server's Name, on page 2004

Step 1 If you haven't done so already, log in to the Firepower Management Center and click **System** > **Integration** > **Realms**.

Step 2 On Realms page, click the name of the realm for which to configure a directory.

Step 3 On Directory page, click **Add Directory**.

Step 4 Enter the **Hostname / IP Address** and **Port** for the LDAP server or Active Directory domain controller.
The system sends an LDAP query to the hostname or IP address you specify. If the host name resolves to the IP address of an LDAP server or Active Directory domain controller, the **Test** succeeds.

Step 5 Select an **Encryption Mode**.

Step 6 Choose an **SSL Certificate** from the list or click **Add** ( ) to add a certificate.

Step 7 To test the connection, click **Test**.

Step 8 Click **OK**.

Step 9 Click **Save**. You are returned to Realms page

Step 10 If you haven't already enabled the realm, on Realms page, slide **State** to enabled.

What to do next

- Download Users and Groups, on page 2007.

Related Topics

Export the Active Directory Server's Root Certificate, on page 2004

Find the Active Directory Server's Name, on page 2004

Download Users and Groups

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	Control	Any	Any	Administrator, Access Admin, Network Admin

This section discusses how to download users and groups from your Active Directory server to the Firepower Management Center. If you do not specify any groups to include, the system retrieves user data for all the groups that match the parameters you provided. For performance reasons, Cisco recommends that you explicitly include only the groups that represent the users you want to use in access control.

The maximum number of users the Firepower Management Center can retrieve from the server depends on your Firepower Management Center model. If the download parameters in your realm are too broad, the Firepower Management Center obtains information on as many users as it can and reports the number of users it failed to retrieve in Task of the Message Center.

For more information about realm configuration fields, see Realm Fields, on page 1999.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration** > **Realms**.

Step 3 To download users and groups manually, click **Download** ( ) next to the realm to download users and user groups. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. You can skip the remainder of this procedure.

Step 4 To configure the realm for automatic user and group download, click **Edit** ( ) next to the realm to configure for automatic user and group download.

Step 5 On User Access Control page, check **Download users and groups (required for user access control)**.

Step 6 Select a time to **Begin automatic download at** from the lists.

Step 7 Select a download interval from the **Repeat Every** list.

Step 8 To include or exclude user groups from the download, choose user groups from the **Available Groups** column and click **Add to Include** or **Add to Exclude**.

Separate multiple users with commas. You can also use an asterisk (*) as a wildcard character in this field.

Note You must **Add to Include** if you want to perform user control on users in that group.

Use the following guidelines:

- If you leave a group in the **Available Groups** box, the group is not downloaded.
- If you move a group to the **Add to Include** box, the group is downloaded and user data is available for user awareness and user control.
- If you move a group to the **Add to Exclude** box, the group is downloaded and user data is available for user awareness, but not for user control.
- To include users from groups that are not included, enter the user name in the field below **Groups to Include** and click **Add**.

- To exclude users from groups that are not excluded, enter the user name in the field below **Groups to Exclude** and click **Add**.

Manage a Realm

This section discusses how to perform various maintenance tasks for a realm using controls on the Realms page. Note the following:

- If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration**.

Step 3 Click **Realms**.

Step 4 To delete a realm, click **Delete** ( ).

Step 5 To edit a realm, click **Edit** ( ) next to the realm and make changes as described in Create a Realm, on page 1997.

Step 6 To enable a realm, slide **State** to the right; to disable a realm, slide it to the left.

Step 7 To download users and user groups, click **Download** ( ).

Step 8 To copy a realm, click **Copy** ( ).

Step 9 To compare realms, see Compare Realms, on page 2008.

Compare Realms

You must be an Admin, Access Admin, Network Admin, or Security Approver to perform this task.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration**.

Step 3 Click **Realms**.

Step 4 Click **System** > **Integration**.

Step 5 Click **Realms**.

Step 6 Click **Compare Realms**.

Step 7 Choose **Compare Realm** from the **Compare Against** list.

Step 8 Choose the realms you want to compare from the **Realm A** and **Realm B** lists.

Step 9 Click **OK**.

Step 10 To navigate individually through changes, click **Previous** or **Next** above the title bar.

Step 11 (Optional.) Click **Comparison Report** to generate the realm comparison report.

Step 12 (Optional.) Click **New Comparison** to generate a new realm comparison view.

Troubleshoot Realms and User Downloads

If you notice unexpected server connection behavior, consider tuning your realm configuration, device settings, or server settings. For other related troubleshooting information, see:

- Troubleshoot the User Agent Identity Source, on page 2058
- Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2029
- Troubleshoot the TS Agent Identity Source, on page 2052
- Troubleshoot the Captive Portal Identity Source, on page 2044
- Troubleshoot the Remote Access VPN Identity Source, on page 2048
- Troubleshoot User Control, on page 415

Symptom: Realms and groups reported but not downloaded

The Firepower Management Center's health monitor informs you of user or realm mismatches, which are defined as:

- User mismatch: A user is reported to the Firepower Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Firepower Management Center. Review the information discussed in Realm Fields, on page 1999.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firepower Management Center.

For example, if you defined a realm that corresponds to a domain named **domain.example.com** in the Firepower Management Center but a login is reported from a domain named **another-domain.example.com**, this is a *realm mismatch*. Users in this domain are identified by the Firepower Management Center as Unknown.

You set the mismatch threshold as a percentage, above which a health warning is triggered. Examples:

- If you use the default mismatch threshold of 50%, and there are two mismatched realms in eight incoming sessions, the mismatch percentage is 25% and no warning is triggered.
- If you set the mismatch threshold to 30% and there are three mismatched realms in five incoming sessions, the mismatch percentage is 60% and a warning is triggered.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

For more information, see Detect Realm or User Mismatches, on page 2012.

Symptom: Access control policy doesn't match group membership

This solution applies to an AD domain that is in a trust relationship with other AD domains. In the following discussion, *external domain* means a domain other than the one to which the user logs in.

If a user belongs to a group defined in a trusted external domain, Firepower doesn't track membership in the external domain. For example, consider the following scenario:

- Domain controllers 1 and 2 trust each other
- Group A is defined on domain controller 2
- User `mparvinder` in controller 1 is a member of Group A

Even though user `mparvinder` is in Group A, the Firepower access control policy rules specifying membership Group A don't match.

Solution: Create a similar group in domain controller 1 that contains has all domain 1 accounts that belong to group A. Change the access control policy rule to match any member of Group A or Group B.

Symptom: Access control policy doesn't match child domain membership

If a user belongs to a domain that is child of parent domain, Firepower doesn't track the parent/child relationships between domains. For example, consider the following scenario:

- Domain `child.parent.com` is child of domain `parent.com`
- User `mparvinder` is defined in `child.parent.com`

Even though user `mparvinder` is in a child domain, the Firepower access control policy matching the `parent.com` don't match `mparvinder` in the `child.parent.com` domain.

Solution: Change the access control policy rule to match membership in either `parent.com` or `child.parent.com`.

Symptom: Realm or realm directory test fails

The **Test** button on the directory page sends an LDAP query to the hostname or IP address you entered. If it fails, check the following:

- The **Hostname** you entered resolves to the IP address of an LDAP server or Active Directory domain controller.
- The **IP Address** you entered is valid.

The **Test AD Join** button on the realm configuration page verifies the following:

- DNS resolves the **AD Primary Domain** to an LDAP server or Active Directory domain controller's IP address.
- The **AD Join Username** and **AD Join Password** are correct.

  AD Join Username must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).
- The user has sufficient privileges to create a computer in the domain and join the Firepower Management Center to the domain as a Domain Computer.

Symptom: User timeouts are occurring at unexpected times

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your user agent or ISE server is synchronized with the time on the Firepower Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC, user agent, or TS Agent server is synchronized with the time on the Firepower Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

Symptom: Users are not included or excluded as specified in your realm configuration

If you configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft Windows servers limit the number of users they report:

- 5000 users per group on Microsoft Windows Server 2008 or 2012

If necessary, you can modify your server configuration to increase this default limit and accommodate more users.

Symptom: Users are not downloaded

Possible causes follow:

- If you have the realm **Type** configured incorrectly, users and groups cannot be downloaded because of a mismatch between the attribute the Firepower system expects and what the repository provides. For example, if you configure **Type** as **LDAP** for a Microsoft Active Directory realm, the Firepower system expects the `uid` attribute, which is set to `none` on Active Directory. (Active Directory repositories use `sAMAccountName` for the user ID.)

  Solution: Set the realm **Type** field appropriately: **AD** for Microsoft Active Directory or **LDAP** for another supported LDAP repository.

- Users in Active Directory groups that have special characters in the group or organizational unit name might not be available for identity policy rules. For example, if a group or organizational unit name contains the characters asterisk (*), equals (=), or backslash (\), users in those groups are not downloaded and can't be used for identity policies.

  Solution: Remove special characters from the group or organizational unit name.

Symptom: User data for previously-unseen ISE and User Agent users is not displaying in the web interface

After the system detects activity from an ISE/ISE-PIC, user agent, or TS Agent user whose data is not yet in the database, the system retrieves information about them from the server. In some cases, the system requires additional time to successfully retrieve this information from Microsoft Windows servers. Until the data retrieval succeeds, activity seen by the ISE/ISE-PIC, user agent, or TS Agent user is **not** displayed in the web interface.

Note that this may also prevent the system from handling the user's traffic using access control rules.

Symptom: User data in events is unexpected

If you notice user or user activity events contain unexpected IP addresses, check your realms. The system does not support configuring multiple realms with the same **AD Primary Domain** value.

Symptom: Users originating from terminal server logins are not uniquely identified by the system

If your deployment includes a terminal server and you have a realm configured for one or more servers connected to the terminal server, you must deploy the Cisco Terminal Services (TS) Agent to accurately report user logins in terminal server environments. When installed and configured, the TS Agent assigns unique ports to individual users so the Firepower System can uniquely identify those users in the web interface.

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Detect Realm or User Mismatches

This section discusses how to detect realm or user *mismatches*, which are defined as:

- User mismatch: A user is reported to the Firepower Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Firepower Management Center. Review the information discussed in Realm Fields, on page 1999.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firepower Management Center.

For additional details, see Troubleshoot Realms and User Downloads, on page 2009.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

Step 1 Enable detection of realm or user mismatches:

a) Log in to the Firepower Management Center if you have not already done so.
b) Click **System** > **Health** > **Policy**.
c) Create a new health policy or edit an existing one.
d) On the Editing Policy page, set a **Policy Runtime Interval**.
This is the frequency at which all health monitor tasks run.
e) In the left pane, cick **Realm**.
f) Enter the following information:

- **Enabled**: Click **On**
- **Warning Users match threshold %**: The percentage of either realm mismatches or user mismatches that triggers a warning in the Health Monitor. For more information, see Troubleshoot Realms and User Downloads, on page 2009.

g) At the bottom of the page, click **Save Policy & Exit**.
h) Apply the health policy to managed devices as discussed in Applying Health Policies, on page 305.

Step 2 View user and realm mismatches in any of the following ways:

- If the warning threshold is exceeded, click **Warning** > **Health** in the top navigation of the Firepower Management Center. This opens the Health Monitor.
- Click **System** > **Health** > **Monitor**.

Step 3 On the Health Monitor page, in the Display column, expand **Realm: Domain** or **Realm: User** to view details about the mismatch.

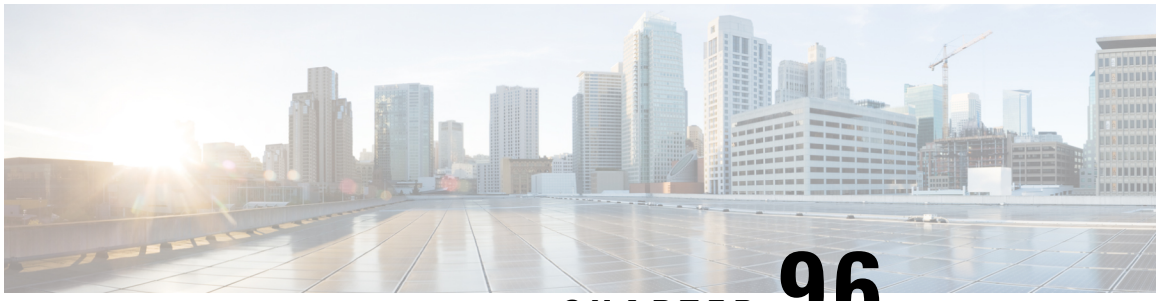
History for Realms

Feature	Version	Details
Realms for user control.	—	Feature introduced before Version 6.0. A realm is a connection between the FMC either an Active Directory or LDAP user repository.



CHAPTER 96

Control Users with ISE/ISE-PIC

The following topics discuss how to perform user awareness and user control with ISE/ISE-PIC:

The ISE/ISE-PIC Identity Source

You can integrate your Cisco Identity Services Engine (ISE) or ISE Passive Identity Connector (ISE-PIC) deployment with the Firepower System to use ISE/ISE-PIC for passive authentication.

ISE/ISE-PIC is an authoritative identity source, and provides user awareness data for users who authenticate using Active Directory (AD), LDAP, RADIUS, or RSA. Additionally, you can perform user control on Active Directory users. ISE/ISE-PIC does not report failed login attempts or the activity of ISE Guest Services users.

Note The Firepower System does not parse IEEE 802.1x machine authentication but it *does* parse 802.1x user authentication. If you are using 802.1x with ISE, you must include user authentication. 802.1x machine authentication will not provide a user identity to the FMC that can be used in policy.

For more information on Cisco ISE/ISE-PIC, see the *Cisco Identity Services Engine Administrator Guide* and the *Identity Services Engine Passive Identity Connector (ISE-PIC) Installation and Administrator Guide*.

Note We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set and the most number of issue fixes.

Destination Security Group Tag (SGT) Matching

If you use ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects.

Matching on SGT tags provides the following benefits:

- The FMC can subscribe to Security Group Tag eXchange Protocol (SXP) mappings from ISE.

  ISE uses SXP to propagate the IP-to-SGT mapping database to managed devices. When you configure FMC to use an ISE server, you enable the option to listen to the SXP topic from ISE. This causes the FMC to learn about the security group tags and mappings directly from ISE. The FMC then publishes SGTs and mappings to managed devices.

  The SXP Topic receives security group tags based on static and dynamic mappings learned through the SXP protocol between ISE and other SXP compliant devices (like switches).

  You can create security group tags in ISE and assign host or network IP addresses to each tag. You can also assign SGTs to user accounts, and the SGT is assigned to the user's traffic. If the switches and routers in the network are configured to do so, these tags then get assigned to packets as they enter the network controlled by ISE, the Cisco TrustSec cloud.

  SXP is *not* supported by ISE-PIC.

- The FMC and managed FTD devices can learn about SGT mappings without deploying additional policy. (In other words, you can view connection events for SGT mappings without deploying an access control policy.)

- Supports Cisco TrustSec, which enables you to segment your network to protect critical business assets.

- When a managed device evaluates SGT as a traffic matching criteria for an access control rule, it uses the following priority:

  1. The source SGT tag defined in the packet, if any.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

  2. The SGT assigned to the user session, as downloaded from the ISE session directory. The SGT can be matched to source or destination.

  3. The SGT-to-IP address mapping downloaded using SXP. If the IP address is in the range for an SGT, then the traffic matches the access control rule that uses the SGT. The SGT can be matched to source or destination.

Examples:

- In ISE, create an SGT tag named Guest Users and associate it with the 192.0.2.0/24 network.

  For example, you could use Guest Users as a source SGT condition in your access control rule and restrict access to certain URLs, web site categories, or networks from anyone who accesses your network.

- In ISE, create an SGT tag named Restricted Networks and associate it with the 198.51.100.0/8 network.

For example, you could use Restricted Networks as a destination SGT rule condition and block access from Guest Users and other networks that have users who are not authorized to access the network.

ISE/ISE-PIC Guidelines and Limitations

Use the guidelines discussed in this section when configuring ISE/ISE-PIC with the Firepower System.

ISE/ISE-PIC Version and Configuration Compatibility

Your ISE/ISE-PIC version and configuration affects its integration and interaction with Firepower, as follows:

- We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set.
- Synchronize the time on the ISE/ISE-PIC server and the Firepower Management Center. Otherwise, the system might perform user timeouts at unexpected intervals.

- To implement user control using ISE or ISE-PIC data, configure and enable a realm for the ISE server assuming the pxGrid persona as described in Create a Realm, on page 1997.
- Each Firepower Management Center host name that connects to an ISE server must be unique; otherwise, the connection to one of the Firepower Management Centers will be dropped.
- If ISE Endpoint Protection Service (EPS) is enabled and configured in your ISE deployment, you can use your ISE connection to run ISE EPS remediations on the source or destination host involved in a correlation policy violation.
- If you configured your ISE deployment to update a user's SGT after the user's EPSStatus changes, your ISE EPS remediations also update the SGT on the Firepower Management Center.
- ISE-PIC does not provide ISE attribute data or support ISE EPS remediations.

For the specific versions of ISE/ISE-PIC that are compatible with this version of the system, see the *Cisco Firepower Compatibility Guide*.

IPv6 support

Version 2.0 (patch 4) and later of ISE/ISE-PIC includes support for IPv6-enabled endpoints.

Approve clients in ISE

Before a connection between the ISE server and the Firepower Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.

Security Group Tags (SGT)

A Security Group Tag (SGT) specifies the privileges of a traffic source within a trusted network. Cisco ISE and Cisco TrustSec use a feature called Security Group Access (SGA) to apply SGT attributes to packets as they enter the network. These SGTs correspond to a user's assigned security group within ISE or TrustSec. If you configure ISE as an identity source, the Firepower System can use these SGTs to filter traffic.

Security Group Tags can be used both as source and destination matching criteria in access control rules.

Note To implement user control using only the ISE SGT attribute tag, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy. For more information, see Configuring ISE Attribute Conditions, on page 414.

Note In some rules, custom SGT conditions can match traffic tagged with SGT attributes that were *not* assigned by ISE. This is not considered user control, and works only if you are not using ISE/ISE-PIC as an identity source; see Custom SGT Conditions, on page 417.

To match destination SGT tags in addition to source SGT tags, the following apply:

Required ISE version: 2.2 patch 1 or later

Recommended ISE version: 2.6 or later

Router support: Any Cisco router that supports SGT inline tagging over Ethernet. For more information, consult a reference such as the Cisco Group Based Policy Platform and Capability Matrix Release

Limitations:

- Quality of Service (QoS) policy uses source SGT matching only; it does *not* use destination SGT matching
- RA-VPN does not receive SGT mappings directly through RADIUS

If your FMC is managing an ASA with FirePOWER Services device, SXP subscriptions work only if a captive portal identity rule is deployed to the device.

ISE and High Availability

When the primary Firepower Management Center fails, the following occur:

- Until the standby is promoted to primary, the user database on the secondary Firepower Management Center is read-only.

  Users added to the repository (for example, Active Directory) are not downloaded to the Firepower Management Center and those users are identified as Unknown.

  New SGTs are not used.

- After the standby is promoted to primary, all operations return to normal; that is, users are downloaded, new SGTs are used, and users are identified if possible.

When the ISE primary server fails, you must manually promote the secondary to primary; there is no automatic failover.

Endpoint Location (or Location IP)

An Endpoint Location attribute is the IP address of the network device that used ISE to authenticate the user, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Location (Location IP)**.

ISE Attributes

Configuring an ISE connection populates the Firepower Management Center database with ISE attribute data. You can use the following ISE attributes for user awareness and user control. This is not supported with ISE-PIC.

Endpoint Profile (or Device Type)

An Endpoint Profile attribute is the user's endpoint device type, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Profile (Device Type)**.

How to Configure ISE/ISE-PIC for User Control

You can use ISE/ISE-PIC in any of the following configurations:

- With a realm, identity policy, and associated access control policy.

  Use a realm to control *user* access to network resources in policy. You can still use ISE/ISE-PIC Security Group Tags (SGT) metadata in your policies.

- With an access control policy only. No realm or identity policy are necessary.

  Use this method to control network access using SGT metadata alone.

How to Configure ISE Without a Realm

This topic provides a high-level overview of tasks you must complete to configure ISE to be able to allow or block access to the network using SGT tags.

Procedure

	Command or Action	Purpose
Step 1	SGT matching: Enable SXP on ISE.	This enables the FMC to receive updates from ISE when SGT metadata changes.
Step 2	Export system certificates from ISE/ISE-PIC.	The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the FMC. See Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024
Step 3	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See Configure ISE/ISE-PIC for User Control, on page 2026.
Step 4	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Introduction to Access Control Rules, on page 1271.
Step 5	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See Deploy Configuration Changes, on page 374.

What to do next

Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024

How to Configure ISE/ISE-PIC for User Control Using a Realm

Before you begin

This topic provides a high-level overview of tasks you must complete to configure ISE/ISE-PIC for user control and to be able to allow or block user or group access to the network. Users and groups can be stored in any server listed in Supported Servers for Realms, on page 1995.

Procedure

	Command or Action	Purpose
Step 1	Destination SGT only: Enable SXP on ISE.	This enables the FMC to receive updates from ISE when SGT metadata changes.
Step 2	Export system certificates from ISE/ISE-PIC.	The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the FMC. See Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024
Step 3	Create a realm.	You must create a realm only to control access to the network by the users and groups you choose. See Create a Realm, on page 1997.
Step 4	Download users and groups, and enable the realm.	Downloading users and groups enables you to use them in access control rules. See See Download Users and Groups, on page 2007.
Step 5	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See Configure ISE/ISE-PIC for User Control, on page 2026.
Step 6	Create an identity policy.	An identity policy is a container for one or more identity rules. See Create an Identity Policy, on page 2066.
Step 7	Create an identity rule.	An identity rule specifies how a realm is used to control access to the network by users and groups. See Create an Identity Rule, on page 2063.
Step 8	Associate the identity policy with an access control policy.	This enables the access control policy to use users and groups in the realm.
Step 9	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Introduction to Access Control Rules, on page 1271.
Step 10	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See Deploy Configuration Changes, on page 374.

What to do next

Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024

Configure ISE/ISE-PIC

The following topics discuss how to configure the ISE/ISE-PIC server for use with identity policies in the FMC.

You must export certificates from the ISE/ISE-PIC server to authenticate with the FMC and publish SXP topics so the FMC can be updated with Security Group Tags (SGT) are updated on the ISE server.

Related Topics

Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024
Configure Security Groups and SXP Publishing in ISE, on page 2022

Configure Security Groups and SXP Publishing in ISE

There is a lot of configuration that you must do in Cisco Identity Services Engine (ISE) to create the TrustSec policy and security group tags (SGT). Please look at the ISE documentation for more complete information on implementing TrustSec.

The following procedure picks out the highlights of the core settings you must configure in ISE for the FTD device to be able to download and apply static SGT-to-IP address mappings, which can then be used for source and destination SGT matching in access control rules. See the ISE documentation for detailed information.

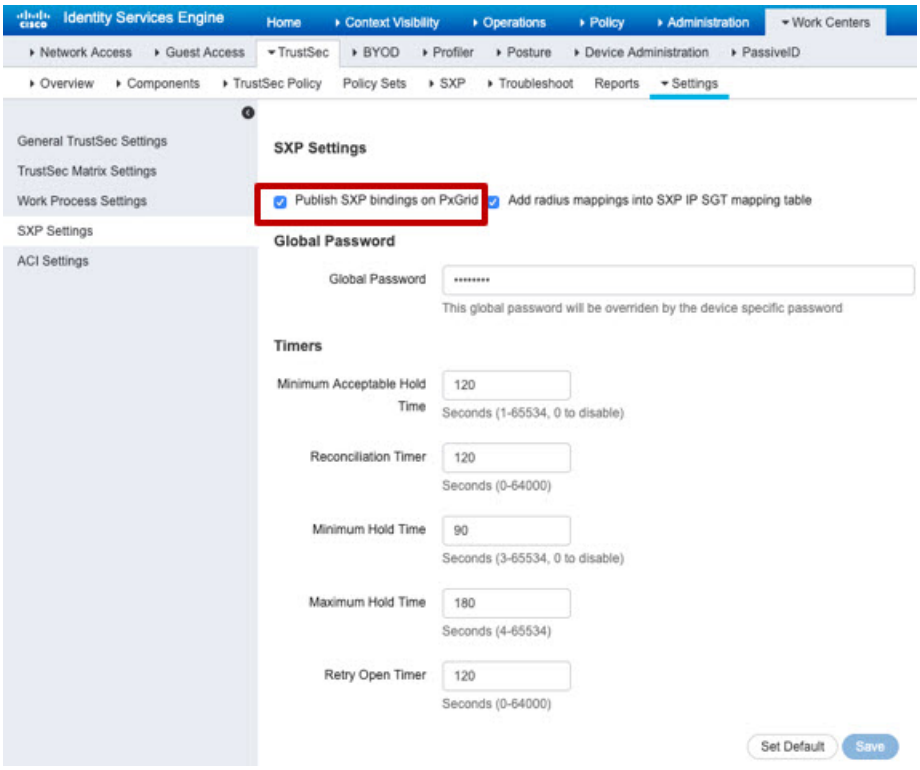
The screen shots in this procedure are based on ISE 2.4. The exact paths to these features might change in subsequent releases, but the concepts and requirements will be the same. Although ISE 2.4 or later is recommended, and preferably 2.6 or later, the configuration should work starting with ISE 2.2 patch 1.

Before you begin

You must have the ISE Plus license to publish SGT-to-IP address static mappings and to get user session-to-SGT mappings so that the FTD device can receive them.

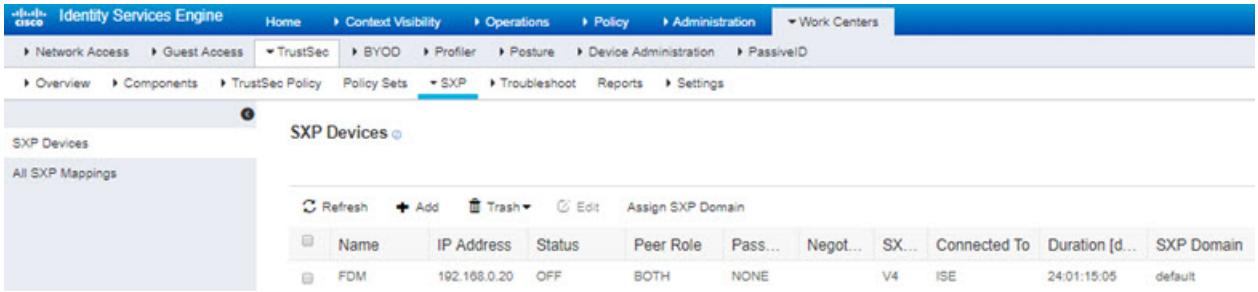
Step 1 Choose **Work Centers** > **TrustSec** > **Settings** > **SXP Settings**, and select the **Publish SXP Bindings on PxGrid** option.

This option makes ISE send the SGT mappings out using SXP. You must select this option for the FTD device to “hear” anything from listing to the SXP topic. This option must be selected for the FTD device to get static SGT-to-IP address mapping information. It is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

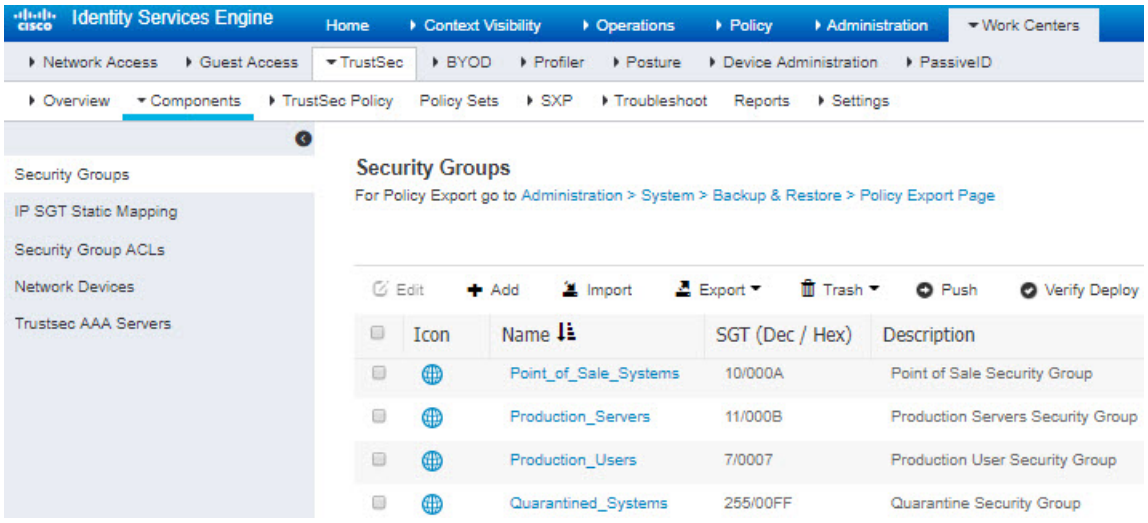


Step 2 Choose **Work Centers** > **TrustSec** > **SXP** > **SXP Devices**, and add a device.

This does not have to be a real device, you can even use the management IP address of the FTD device. The table simply needs at least one device to induce ISE to publish the static SGT-to-IP address mappings. This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

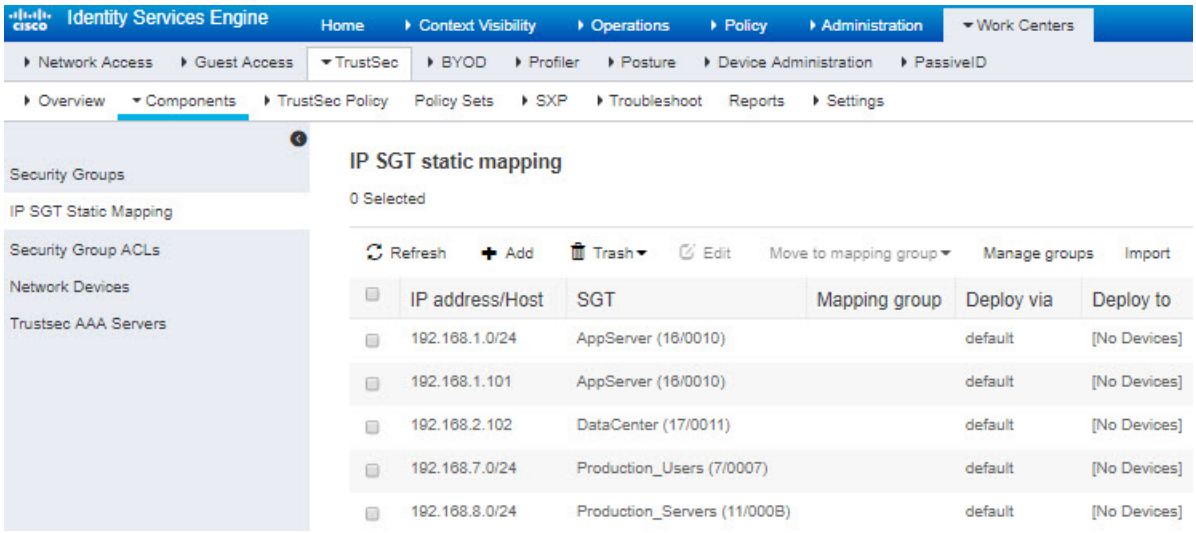


Step 3 Choose **Work Centers** > **TrustSec** > **Components** > **Security Groups** and verify there are security group tags defined. Create new ones as necessary.



Step 4 Choose **Work Centers** > **TrustSec** > **Components** > **IP SGT Static Mapping** and map host and network IP addresses to the security group tags.

This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Export Certificates from the ISE/ISE-PIC Server for Use in the FMC

The following sections discuss how to:

- Export system certificates from the ISE/ISE-PIC server.

  These certificates are required to securely connect to the ISE/ISE-PIC server. You might need to export one, or as many as three, certificates, depending on how your ISE system is set up:

  - One certificate for the pxGrid server

- One certificate for the monitoring (MNT) server
- One certificate, including the private key, for the FMC

- Import these certificates into the FMC.

Related Topics

Export a System Certificate, on page 2025
Import ISE/ISE-PIC Certificates, on page 2025

Export a System Certificate

You can export a system certificate or a certificate and its associated private key. If you export a certificate and its private key for backup purposes, you can reimport them later if needed.

Before you begin

To perform the following task, you must be a Super Admin or System Admin.

Step 1 Choose **Administration** > **System** > **Certificates** > **System Certificates**.

Step 2 Check the check box next to the certificate that you want to export and click **Export**.

Step 3 Choose whether to export only the certificate, or the certificate and its associated private key.

Tip We do not recommend exporting the private key that is associated with a certificate because its value may be exposed. If you must export a private key (for example, when you export a wildcard system certificate to be imported into the other Cisco ISE nodes for inter-node communication), specify an encryption password for the private key. You must specify this password while importing this certificate into another Cisco ISE node to decrypt the private key.

Step 4 Enter the password if you have chosen to export the private key. The password should be at least eight characters long.

Step 5 Click **Export** to save the certificate to the file system that is running your client browser.

If you export only the certificate, the certificate is stored in the PEM format. If you export both the certificate and private key, the certificate is exported as a .zip file that contains the certificate in the PEM format and the encrypted private key file.

Import ISE/ISE-PIC Certificates

This procedure is optional. You can also import ISE server certificates when you create the ISE/ISE-PIC identity source as discussed in Configure ISE/ISE-PIC for User Control, on page 2026.

Before you begin

Export certificates from the ISE/ISE-PIC server as discussed in Export a System Certificate, on page 2025. The certificates and key must be present on the machine from which you log in to the FMC.

You import two types of certificate objects:

- An internal certificate and private key for the FMC to authenticate with ISE/ISE-PIC.

- One or more trusted certificates authorities (CAs) for pxGrid and your ISE monitoring (MNT) server.

  Depending on how you set up your ISE/ISE-PIC system, this could be two separate certificates or one certificate.

Step 1 Log in to the FMC if you have not already done so.
Step 2 Click **Objects** > **Object Management**.
Step 3 Expand **PKI**.
Step 4 Click **Internal Certs**.
Step 5 Click **Add Internal Cert**.
Step 6 Follow the prompts on your screen to import the certificate and private key.
Step 7 Click **Trusted CAs**.
Step 8 Click **Add Trusted CA**.
Step 9 Follow the prompts on your screen to import the pxGrid server certificate.
Step 10 Repeat the preceding steps, if necessary, to import the MNT server's trusted CA.

What to do next

Configure ISE/ISE-PIC for User Control, on page 2026

Configure ISE/ISE-PIC for User Control

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the ISE server, assuming the pxGrid persona, as discussed in Create a Realm, on page 1997.
- Configure a connection to ISE or ISE-PIC. For more information, see The ISE/ISE-PIC Identity Source, on page 2015 and ISE/ISE-PIC Configuration Fields, on page 2028.
- To get all mappings that are defined in ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from ISE, skip the steps discussed in Create and Edit Access Control Rules, on page 1276. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
  - To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.
- Export certificates from the ISE/ISE-PIC server and optionally import them into the FMC as discussed in Export Certificates from the ISE/ISE-PIC Server for Use in the FMC, on page 2024.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration**.

Step 3 Click **Identity Sources**.

Step 4 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note To disable the connection, click **None**.

Step 5 Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.

Step 6 Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **FMC Server Certificate** list. You can also click **Add** ( ) to add a certificate.

Note The **FMC Server Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

Step 7 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 8 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 9 To test the connection, click **Test**.

If the test fails, click **Additional Logs** for more information about the connection failure.

Note When you run two ISE pxGrid 1.0 nodes, it is normal for one host to show Success and one to show Failure. Because pxGrid 1.0 only runs actively on one ISE node at a time, the likelihood of success depends on which node in ISE is the active pxGrid node.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2066.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1267.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 374.
- Monitor user activity as discussed in Using Workflows, on page 2294.

Related Topics

Trusted Certificate Authority Objects, on page 481
Internal Certificate Objects, on page 484

ISE/ISE-PIC Configuration Fields

The following fields are used to configure a connection to ISE/ISE-PIC.

Primary and Secondary Host Name/IP Address

The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers.

The ports used by the host names you specify must be reachable by both ISE and the Firepower Management Center.

pxGrid Server CA

The certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.

MNT Server CA

The certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

FMC Server Certificate

The certificate and key that the Firepower Management Center must provide to ISE/ISE-PIC to connect to ISE/ISE-PIC or to perform bulk downloads.

Note The **FMC Server Certificate** must include the clientAuth extended key usage value, or it must not include any extended key usage values.

ISE Network Filter

An optional filter you can set to restrict the data that ISE reports to the Firepower Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in the following ways:

- Leave the field blank to specify **`any`**.
- Enter a single IPv4 address block using CIDR notation.
- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

Note This version of the Firepower System does not support filtering using IPv6 addresses, regardless of your ISE version.

Subscribe to:

Session Directory Topic: Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata.

SXP Topic: Check this box to subscribe to SXP mappings from the ISE server.

Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues

Troubleshoot Cisco TrustSec issues

A device interface can be configured to propagate Security Group Tags (SGTs) either from ISE/ISE-PIC or from a Cisco device on the network (referred to as Cisco TrustSec.) On the device management page (**Devices** > **Device Management**), the **Propagate Security Group Tag** check box for an interface is checked after a device reboot. If you do not want the interface to propagate TrustSec data, uncheck the box.

Troubleshoot ISE/ISE-PIC issues

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2009 and Troubleshoot User Control, on page 415.

If you experience issues with the ISE or ISE-PIC connection, check the following:

- The pxGrid Identity Mapping feature in ISE must be enabled before you can successfully integrate ISE with the Firepower System.
- When the primary server fails, you must manually promote the secondary to primary; there is no automatic failover.
- Before a connection between the ISE server and the Firepower Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

  You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.
- The **FMC Server Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.
- The time on your ISE server must be synchronized with the time on the Firepower Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.
- If your deployment includes a primary and a secondary pxGrid node,
  - The certificates for both nodes must be signed by the same certificate authority.
  - The ports used by the host name must be reachable by both the ISE server and by the Firepower Management Center.
- If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

To exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE, use the **configure identity-subnet-filter** {**add** | **remove**} command. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

If you experience issues with user data reported by ISE or ISE-PIC, note the following:

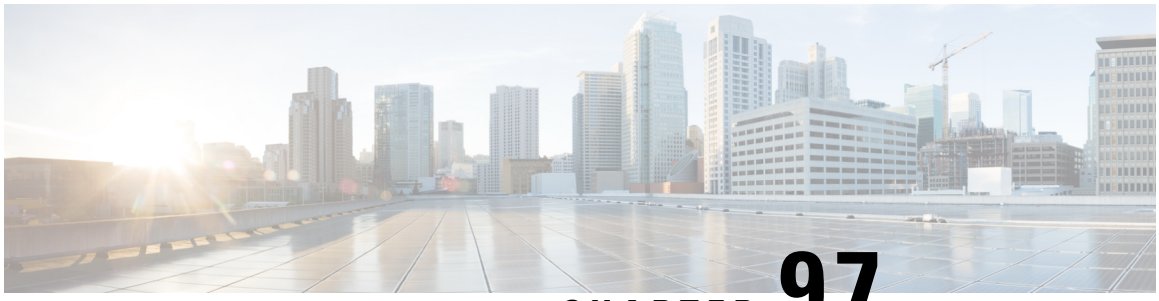
- After the system detects activity from an ISE user whose data is not yet in the database, the system retrieves information about them from the server. Activity seen by the ISE user is *not* handled by access control rules, and is *not* displayed in the web interface until the system successfully retrieves information about them in a user download.

- You cannot perform user control on ISE users who were authenticated by an LDAP, RADIUS, or RSA domain controller.
- The Firepower Management Center does not receive user data for ISE Guest Services users.
- If ISE monitors the same users as TS Agent, the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and ISE report identical activity from the same IP address, only the TS Agent data is logged to the Firepower Management Center.
- Your ISE version and configuration impact how you can use ISE in the Firepower System. For more information, see The ISE/ISE-PIC Identity Source, on page 2015.
- If you have Firepower Management Center high availability configured and the primary fails, see the section on ISE and High Availability in ISE/ISE-PIC Guidelines and Limitations, on page 2017.
- ISE-PIC does not provide ISE attribute data.
- ISE-PIC cannot perform ISE EPS remediations.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

If you experience issues with supported functionality, see The ISE/ISE-PIC Identity Source, on page 2015 for more information about version compatibility.

History for ISE/ISE-PIC

Feature	Version	Details
Destination Security Group Tag matching (SGT)	6.5.0	Feature introduced. Enables you to use ISE SGT tags for both source and destination matching criteria in access control rules. SGT tags are tag-to-host/network mappings obtained by ISE. New/modified screens: • New options to configure Destination SGT matching: **System** > **Integration** > **Identity Sources** > **ISE/ISE-PIC** • **Session Directory Topic**: Subscribe to ISE user session information. • **SXP Topic**: Subscribe to SGT tag updates on the ISE server. • New and renamed columns in **Analysis** > **Connections** > **Events** • Renamed: Security Groups Tags renamed to Source SGT • New: Destination SGT
Integration with ISE-PIC	6.2.1	You can now use data from ISE-PIC.
SGT tags for user control.	6.2.0	You no longer need to create a realm or identity policy to perform user control based on ISE Security Group Tag (SGT) data.
Integration with ISE.	6.0	Feature introduced. By subscribing to Cisco's Platform Exchange Grid (PxGrid), the Firepower Management Center can download additional user data, device type data, device location data, and Security Group Tags (SGTs) —a method used by ISE to provide network access control).



CHAPTER 97

Control Users with Captive Portal

The Captive Portal Identity Source

Captive portal is one of the authoritative identity sources supported by the Firepower System. It is an active authentication method where users authenticate onto the network using a managed device.

You typically use captive portal to require authentication to access the internet or to access restricted internal resources; you can optionally configure guest access to resources. After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only.

Note HTTPS traffic must be decrypted before captive portal can perform authentication.

Captive portal also records failed authentication attempts. A failed attempt does not add a new user to the list of users in the database. The user activity type for failed authentication activity reported by captive portal is **Failed Auth User**.

The authentication data gained from captive portal can be used for user awareness and user control.

User Roles

- Admin
- Access Admin
- Network Admin

Captive Portal Guidelines and Limitations

When you configure and deploy captive portal in an identity policy, users from specified realms authenticate through the following device to access your network:

- ASA FirePOWER devices in routed mode running Version 9.5(2) or later
- Firepower Threat Defense devices in routed mode

Note When a remote access VPN user has already actively authenticated through a managed device acting as a secure gateway, captive portal active authentication will not occur, even if configured in an identity policy.

Routed Interface Required

Captive portal active authentication can be performed only by a device with a routed interface configured. If you are configuring the rule for captive portal and your captive portal device contains inline and routed interfaces, you must configure an Interface Conditions to target only the routed interfaces on the device.

If the identity policy referenced by your access control policy contains one or more captive portal identity rules and you deploy the policy on a Firepower Management Center that manages:

- One or more devices with routed interfaces configured, the policy deployment succeeds and the routed interfaces perform active authentication.

  The system does not validate the type of interface in ASA with FirePOWER devices. If you apply a captive portal policy to an inline (tap mode) interface on an ASA with FirePOWER device, the policy deployment succeeds but users in traffic matching those rules are identified as Unknown.

- One or more NGIPSv devices, the policy deployment fails.

Captive Portal and Policies

You configure captive portal in your identity policy and invoke active authentication in your identity rules. Identity policies are associated with access control policies.

You configure some captive portal identity policy settings on the access control policy's **Active Authentication** tab page and configure the rest in an identity rule associated with the access control policy.

Captive portal authenticates any user in the associated realm, even if that user does not belong to a downloaded group. The system identifies users in non-downloaded groups as Unknown; Unknown users match no identity rules. To avoid that, configure the realm to download users in all groups you expect to authenticate with captive portal.

To make sure the system downloads all users in a realm, make sure the groups are in the Available Groups list in the realm's configuration.

For more information about users and groups, see Download Users and Groups, on page 2007.

Caution Adding the first or removing the last active authentication rule when SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Captive Portal Requirements and Limitations

Note the following requirements and limitations:

- The system supports up to 20 captive portal logins per second.
- There is a maximum five minute limit between failed login attempts for a failed login attempt to be counted toward the count of maximum login attempts. The five minute limit is not configurable.

  (Maximum login attempts are displayed in connection events: **Analysis** > **Connections** > **Events**.)

  If more than five minutes elapse between failed logins, the user will continue to be redirected to captive portal for authentication, will not be designated a failed login user or a guest user, and will not be reported to the Firepower Management Center.

- Captive portal does not negotiate TLS v1.0 connections.

  Only TLS v1.1 and v1.2 connections are supported.

- The only way to be sure a user logs out is to close and reopen the browser. Unless that happens, in some cases, the user can log out of captive portal and be able to access the network without authenticating again using the same browser.
- If a realm is created for a parent domain and the managed device detects a login to a child of that parent domain, the user's subsequent logout is not detected by the managed device.
- To use an ASA FirePOWER device (in routed mode and running ASA version 9.5(2) or later) for captive portal, use the **captive-portal** ASA CLI command to enable captive portal for active authentication and define the port as described in the *ASA Firewall Configuration Guide* (Version 9.5(2) or later): https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html.
- You must allow traffic destined for the IP address and port of the device you plan to use for captive portal.
- To perform captive portal active authentication on HTTPS traffic, you must use an SSL policy to decrypt the traffic from the users you want to authenticate. You cannot decrypt the traffic in the connection between a captive portal user's web browser and the captive portal daemon on the managed device; this connection is used to authenticate the captive portal user.
- To limit the amount of non-HTTP or HTTPS traffic that is allowed through the managed device, you should enter typical HTTP and HTTPS ports in the identity policy's **Ports** tab page.

  The managed device changes a previously unseen user from **`Pending`** to **`Unknown`** when it determines that the incoming request does not use the HTTP or HTTPS protocol. As soon as the managed device changes a user from **`Pending`** to another state, access control, Quality of Service, and SSL policies can be applied to that traffic. If your other policies don't permit non-HTTP or HTTPS traffic, configuring ports on the captive portal identity policy can prevent undesired traffic from being allowed through the managed device.

How to Configure the Captive Portal for User Control

High-level overview of how to control user activity with captive portal:

Before you begin

To use the captive portal for active authentication, you must set up an AD or LDAP realm, access control policy, an identity policy, an SSL policy, and associate the identity and SSL policies with the access control policy. Finally, you must deploy the policies to managed devices. This topic provides a high-level summary of those tasks.

An example of the entire procedure begins in Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038.

Perform the following tasks first:

- Confirm that your Firepower Management Center manages one or more devices with a routed interface configured.

  In particular, if your Firepower Management Center manages ASA with FirePOWER devices, see Captive Portal Guidelines and Limitations, on page 2034.

- To use encrypted authentication with the captive portal, either create a PKI object or have your certificate data and key available on the machine from which you're accessing the Firepower Management Center. To create a PKI object, see PKI Objects, on page 476.

Step 1 Create and enable a realm as discussed in the following topics:

- Configure a Realm Directory, on page 2006
- Download Users and Groups, on page 2007

Captive portal authenticates any user in the associated realm, even if that user does not belong to a downloaded group. The system identifies users in non-downloaded groups as Unknown; Unknown users match no identity rules. To avoid that, configure the realm to download users in all groups you expect to authenticate with captive portal.

To make sure the system downloads all users in a realm, make sure the groups are in the Available Groups list in the realm's configuration.

For more information about users and groups, see Download Users and Groups, on page 2007.

Step 2 Create an active authentication identity policy for captive portal.

The identity policy enables selected users in your realm access resources after authenticating with the captive portal.

For more information, see Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038.

Step 3 Configure an access control rule for the captive portal that allows traffic on the captive portal port (by default, TCP 885).

You can choose any available TCP port for the captive portal to use. Whatever your choice, you must create a rule that allows traffic on that port.

For more information, see Configure the Captive Portal Part 2: Create a TCP Port Access Control Rule, on page 2039.

Step 4 Add another access control rule to allow users in the selected realms to access resources using the captive portal.

This enables users to authenticate with captive portal.

For more information, see Configure the Captive Portal Part 3: Create a User Access Control Rule, on page 2040.

Step 5 Configure an SSL decrypt - resign policy for the **Unknown** user so captive portal users can access web pages using the HTTPS protocol.

The captive portal can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the captive portal. Captive portal is seen by the system as the **Unknown** user.

For more information, see Configure Captive Portal Part 4: Create an SSL Decrypt-Resign Policy, on page 2041.

Step 6 Asscociate the identity and SSL policies with the access control policy from step 2.

This final step enables the system to authenticate users with the captive portal.

For more information, see Configure Captive Portal Part 5: Associate Identity and SSL Policies with the Access Control Policy, on page 2042.

What to do next

See Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038.

Configure the Captive Portal Part 1: Create an Identity Policy

Before you begin

This five-part procedure shows how to set up the captive portal using the default TCP port 885 and using a Firepower Management Center server certificate for both the captive portal and for SSL decryption. Each part of this example explains one task required to enable the captive portal to perform active authentication.

If you follow all the steps in this procedure, you can configure captive portal to work for users in your domains. You can optionally perform additional tasks, which are discussed in each part of the procedure.

For an overview of the entire procedure, see How to Configure the Captive Portal for User Control, on page 2036.

Step 1 Log in to the Firepower Management Center if you have not already done so.

Step 2 Click **Policies** > **Access Control** > **Identity** and create or edit an identity policy.

Step 3 (Optional.) Click **Add Category** to add a category for the captive portal identity rules and enter a **Name** for the category.

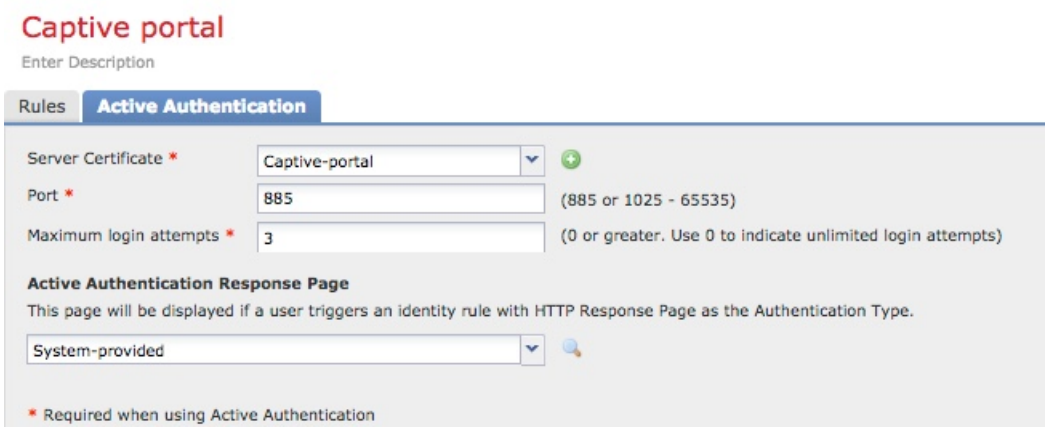
Step 4 Click **Active Authentication**.

Step 5 Choose the appropriate **Server Certificate** from the list or click **Add** ( ) to add a certificate.

Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Step 6 Enter **885** in the **Port** field and specify the **Maximum login attempts**.

Step 7 (Optional.) Choose an **Active Authentication Response Page** as described in Captive Portal Fields, on page 2043. The following figure shows an example.



Step 8 Click **Save**.

Step 9 Click **Rules**.

Step 10 Click **Add Rule** to add a new captive portal identity policy rule, or click **Edit** (✎) to edit an existing rule.

Step 11 Enter a **Name** for the rule.

Step 12 From the **Action** list, choose **Active Authentication**.

The system can enforce captive portal active authentication on HTTP and HTTPS traffic only. If an identity rule **Action** is **Active Authentication** (you are using captive portal) or if you are using passive authentication and you check the option on **Realms & Settings** page to **Use active authentication if passive or VPN identity cannot be established**, use TCP ports constraints only.

Step 13 Click **Realm & Settings**.

Step 14 From the **Realms** list, choose a realm to use for user authentication.

Step 15 (Optional.) Check **Identify as Guest if authentication cannot identify user**. For more information, see Captive Portal Fields, on page 2043.

Step 16 Choose an **Authentication Protocol** from the list.

Step 17 (Optional.) To exempt specific application traffic from captive portal, see Exclude Applications from Captive Portal, on page 2043.

Step 18 Add conditions to the rule (port, network, and so on) as discussed in Rule Condition Types, on page 391.

Step 19 Click **Add**.

Step 20 At the top of the page, click **Save**.

What to do next

Continue with Configure the Captive Portal Part 2: Create a TCP Port Access Control Rule, on page 2039.

Configure the Captive Portal Part 2: Create a TCP Port Access Control Rule

This part of the procedure shows how to create an access control rule that allows the captive portal to communicate with clients using TCP port 885, which is the captive portal's default port. You can choose another port if you wish, but the port must match the one you chose in Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2036.

Step 1 Log in to the Firepower Management Center if you have not already done so.

Step 2 If you haven't done so already, create a certificate for the captive portal as discussed in PKI Objects, on page 476.

Step 3 Click **Policies** > **Access Control** > **Access Control** and create or edit an access control policy.

Step 4 Click **Add Rule**.

Step 5 Enter a **Name** for the rule.

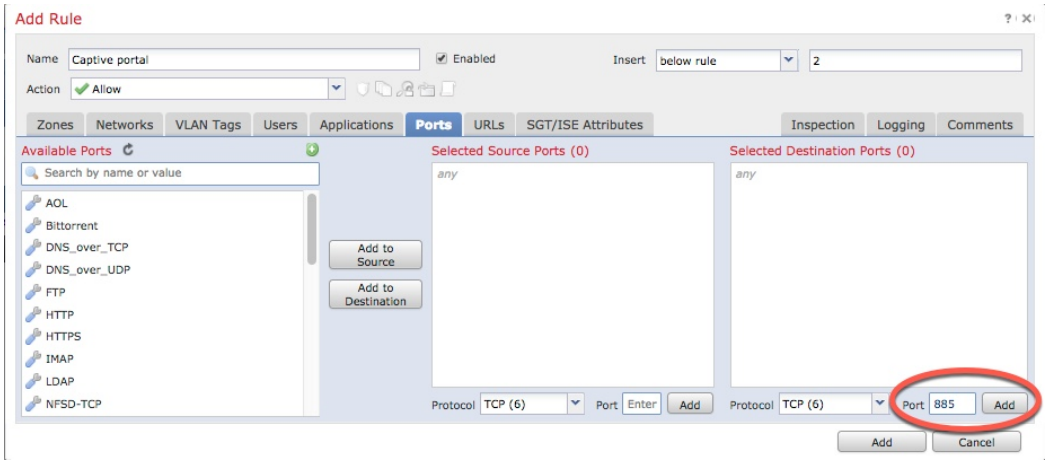
Step 6 Choose **Allow** from the **Action** list.

Step 7 Click **Ports**.

Step 8 From the **Protocol** list under the **Selected Destination Ports** field, choose **TCP**.

Step 9 In the **Port** field, enter **885**.

Step 10 Click **Add** next to the **Port** field.
The following figure shows an example.



Step 11 Click **Add** at the bottom of the page.

What to do next

Continue with Configure the Captive Portal Part 3: Create a User Access Control Rule, on page 2040.

Configure the Captive Portal Part 3: Create a User Access Control Rule

This part of the procedure discusses how to add an access control rule that enables users in a realm to authenticate using captive portal.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2036.

Step 1 In the rule editor, click **Add Rule**.

Step 2 Enter a **Name** for the rule.

Step 3 Choose **Allow** from the **Action** list.

Step 4 Click **Users**.

Step 5 In the **Available Realms** list, click the realms to allow.

Step 6 If no realms display, click **Refresh** ( ).

Step 7 In the **Available Users** list, choose the users to add to the rule and click **Add to Rule**.

Step 8 (Optional.) Add conditions to the access control policy as discussed in Rule Condition Types, on page 391.

Step 9 Click **Add**.

Step 10 On the access control rule page, click **Save**.

Step 11 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic

matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

What to do next

Continue with Configure Captive Portal Part 4: Create an SSL Decrypt-Resign Policy, on page 2041.

Configure Captive Portal Part 4: Create an SSL Decrypt-Resign Policy

This part of the procedure discusses how to create an SSL access policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2036.

Step 1 If you haven't done so already, create a certificate object to decrypt SSL traffic as discussed in PKI Objects, on page 476.

Step 2 Click **Policies** > **Access Control** > **SSL**.

Step 3 Click **New Policy**.

Step 4 Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in SSL Policy Default Actions, on page 1398.

Step 5 Click **Save**.

Step 6 Click **Add Rule**.

Step 7 Enter a **Name** for the rule.

Step 8 From the **Action** list, choose **Decrypt - Resign**.

Step 9 From the **with** list, choose your PKI object.

Step 10 Click **Users**.

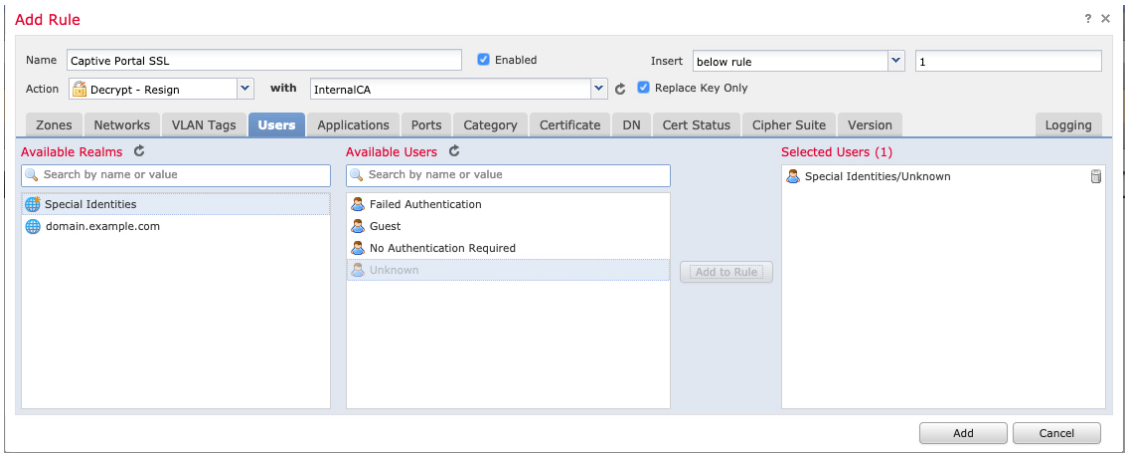
Step 11 Above the **Available Realms** list, click **Refresh** ( ).

Step 12 In the **Available Realms** list, click **Special Identities**.

Step 13 In the **Available Users** list, click **Unknown**.

Step 14 Click **Add to Rule**.

The following figure shows an example.



Step 15 (Optional.) Set other options as discussed in TLS/SSL Rule Conditions, on page 1418.

Step 16 Click **Add**.

Step 17 At the top of the page, click **Save**.

What to do next

Continue with Configure Captive Portal Part 5: Associate Identity and SSL Policies with the Access Control Policy, on page 2042.

Configure Captive Portal Part 5: Associate Identity and SSL Policies with the Access Control Policy

This part of the procedure discusses how to associate the identity policy and SSL **Decrypt - Resign** rule with the access control policy you created earlier. After this, users can authenticate using the captive portal.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2036.

Step 1 Click **Policies** > **Access Control** > **Access Control** and edit the access control policy you created as discussed in Configure the Captive Portal Part 2: Create a TCP Port Access Control Rule, on page 2039. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Either create a new access control policy or edit an existing policy.

Step 3 At the top of the page, click the link next to **Identity Policy**.

Step 4 From the list, choose the name of your identity policy and, at the top of the page, click **Save**.

Step 5 Repeat the preceding steps to associate your captive portal SSL policy with the access control policy.

Step 6 If you haven't done so already, target the policy at managed devices as discussed in Setting Target Devices for an Access Control Policy, on page 1263.

What to do next

- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 374.
- Monitor user activity as discussed in Using Workflows, on page 2294.

Captive Portal Fields

Use the following fields to configure captive portal on the **Active Authentication** tab page of your identity policy. See also Identity Rule Fields, on page 2064 and Exclude Applications from Captive Portal, on page 2043.

Server Certificate

The server certificate presented by the captive portal daemon.

Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Port

The port number to use for the captive portal connection. If you plan to use an ASA FirePOWER device for captive portal, the port number in this field must match the port number you configured on the ASA FirePOWER device using the **captive-portal** CLI command.

Maximum login attempts

The maximum allowed number of failed login attempts before the system denies a user's login request.

Active Authentication Response Page

The system-provided HTTP response page includes **Username** and **Password** fields, as well as a **Login as guest** button to allow users to access the network as guests. To display a single login method, configure a custom HTTP response page.

Choose the following options:

- To use a generic response, click **System-provided**. You can click **View** ( ) to view the HTML code for this page.
- To create a custom response, click **Custom**. A window with system-provided code is displayed that you can replace or modify. When you are done, save your changes. You can edit a custom page by clicking **Edit** ( ).

Related Topics

Internal Certificate Objects, on page 484

Exclude Applications from Captive Portal

You can select applications (identified by their HTTP `User-Agent` strings) and exempt them from captive portal active authentication. This allows traffic from the selected applications to pass through the identity policy without authenticating.

Note Only applications with the **`User-Agent Exclusion` Tag** are displayed in this list.

Step 1 If you haven't done so already, log in to the Firepower Management Center.

Step 2 Click **Policies** > **Access Control** > **Identity** .

Step 3 Edit the identity policy that contains the captive portal rule.

Step 4 On **Realm & Settings** tab page, use the filters in the **Application Filters** list to narrow the applications you want to add to the filter.

- Click the arrow next to each filter type to expand and collapse the list.
- Right-click a filter type and click **Check All** or **Uncheck All**. Note that the list indicates how many filters you have selected of each type.
- To narrow the filters that are displayed, type a search string in the **Search by name** field; this is especially useful for categories and tags. To clear the search, click **Clear** ( ).
- To refresh the filters list and clear any selected filters, click **Reload** ( ).
- To clear all filters and search fields, click **Clear All Filters**.

Note The list displays 100 applications at a time.

Step 5 Choose the applications that you want to add to the filter from the **Available Applications** list:

- To narrow the individual applications that appear, enter a search string in the **Search by name** field. To clear the search, click **Clear** ( ).
- Use paging at the bottom of the list to browse the list of individual available applications.
- To refresh the applications list and clear any selected applications, click **Reload** ( ).

Step 6 Add the selected applications to exclude from external authentication. You can click and drag, or you can click **Add to Rule**. The result is the combination of the application filters you selected.

What to do next

- Continue configuring the identity rule as described in Create an Identity Rule, on page 2063.

Troubleshoot the Captive Portal Identity Source

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2009 and Troubleshoot User Control, on page 415.

If you experience issues with captive portal, check the following:

- The time on your captive portal server must be synchronized with the time on the Firepower Management Center.
- If you have DNS resolution configured and you create an identity rule to perform **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) captive portal, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the hostname you provided when configuring DNS.

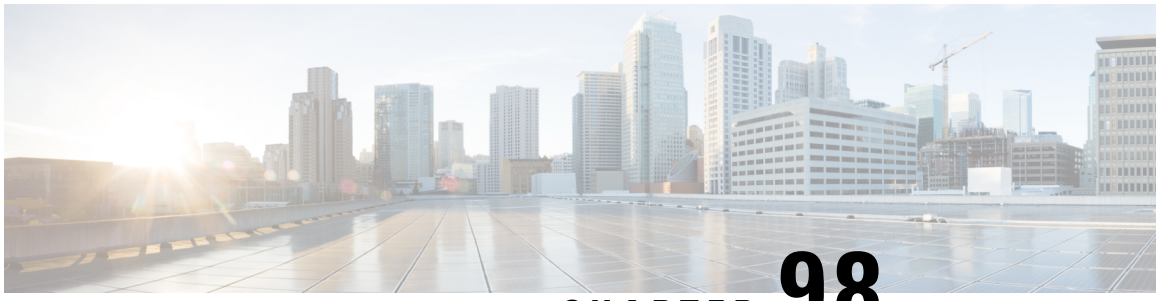
  For ASA with FirePOWER Services and Firepower Threat Defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.
- If you select **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Type** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.
- If you select **`HTTP Basic`** as the **Authentication Type** in an identity rule, users on your network might not notice their sessions time out. Most web browsers cache the credentials from **`HTTP Basic`** logins and use the credentials to seamlessly begin a new session after an old session times out.
- If the connection between your Firepower Management Center and a managed device fails, no captive portal logins reported by the device can be identified during the downtime, unless the users were previously seen and downloaded to the Firepower Management Center. The unidentified users are logged as Unknown users on the Firepower Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.
- If the device you want to use for captive portal contains both inline and routed interfaces, you must configure a zone condition in your captive portal identity rules to target only the routed interfaces on the captive portal device.
- The system does not validate the type of interface in ASA with FirePOWER devices. If you apply a captive portal policy to an inline (tap mode) interface on an ASA with FirePOWER device, the policy deployment succeeds but users in traffic matching those rules are identified as Unknown.
- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.
- The only way to be sure a user logs out is to close and reopen the browser. Unless that happens, in some cases, the user can log out of captive portal and be able to access the network without authenticating again using the same browser.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.
- Captive portal authenticates any user in the associated realm, even if that user does not belong to a downloaded group. The system identifies users in non-downloaded groups as Unknown; Unknown users match no identity rules. To avoid that, configure the realm to download users in all groups you expect to authenticate with captive portal.

  To make sure the system downloads all users in a realm, make sure the groups are in the Available Groups list in the realm's configuration.

  For more information about users and groups, see Download Users and Groups, on page 2007.

History for Captive Portal

Feature	Version	Details
Guest login.	6.1.0	Users can log in as guest using captive portal.
Captive portal.	6.0	Feature introduced. You can use the captive portal to require users to enter their credentials when prompted in a browser window. The mapping also allows policies to be based on a user or group of users.



CHAPTER 98

Control Users with Remote Access VPN

The following topics discuss how to perform user awareness and user control with Remote Access VPN:

The Remote Access VPN Identity Source

Firepower Threat Defense provides secure gateway capabilities that support remote access SSL and IPsec-IKEv2 VPNs. The full tunnel client, AnyConnect Secure Mobility Client, provides secure SSL and IPsec-IKEv2 connections to the security gateway for remote users. AnyConnect is the only client supported on endpoint devices for remote VPN connectivity to Firepower Threat Defense devices.

When you set up a secure VPN gateway as discussed in Create a New Remote Access VPN Policy, on page 885, you can set up an identity policy for those users and associate the identity policy with an access control policy, provided your users are in an Active Directory repository.

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Firepower Threat Defense secure gateway.

Note If users authenticate with RA VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Firepower Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

Configure RA VPN for User Control

Before you begin

- Create a realm as discussed in Create a Realm, on page 1997.
- To use authentication, authorization, and auditing (AAA), set up a RADIUS server group as discussed in RADIUS Server Groups, on page 518.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **Devices** > **VPN** > **Remote Access**.

Step 3 See Create a New Remote Access VPN Policy, on page 885.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2066.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1267.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 374.
- Monitor VPN user traffic as discussed in VPN Session and User Information, on page 932.

Troubleshoot the Remote Access VPN Identity Source

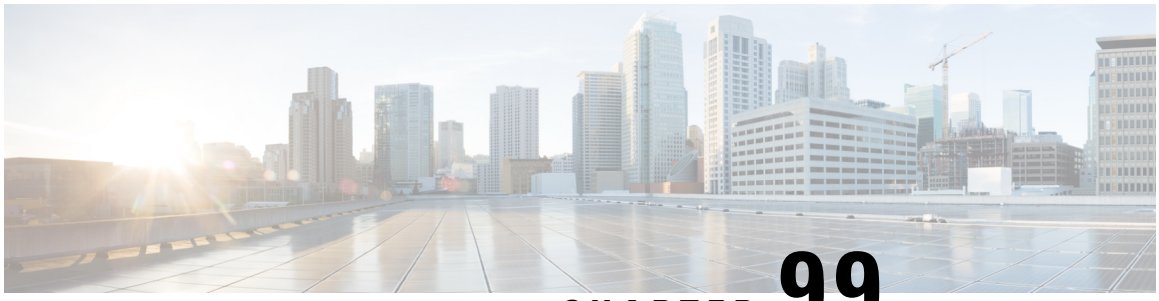
- For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2009, Troubleshoot User Control, on page 415, and VPN Troubleshooting for Firepower Threat Defense, on page 935.
- If you experience issues with Remote Access VPN, check the connection between your Firepower Management Center and a managed device. If the connection fails, all Remote Access VPN logins reported by the device cannot be identified during the downtime, unless the users were previously seen and downloaded to the Firepower Management Center.

  The unidentified users are logged as Unknown users on the Firepower Management Center. After the downtime, the Unknown users are re identified and processed according to the rules in your identity policy.

- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

History for RA VPN

Feature	Version	Details
Remote Access VPN	6.2.1	Feature introduced. RA VPN allows individual users to connect to a private business network from a remote location using a laptop or desktop computer connected to the internet, or an Android or Apple iOS mobile device. Remote users transfer data securely and confidentially using encryption techniques crucial for data being transferred over shared mediums and the Internet.



CHAPTER 99

Control Users with the TS Agent

The following topics discuss how to perform user awareness and user control with TS Agent:

The Terminal Services (TS) Agent Identity Source

The TS Agent is a passive authentication method and one of the authoritative identity sources supported by the Firepower System. A Windows Terminal Server performs the authentication, and the TS Agent reports it to a standalone or high availability Firepower Management Center.

When installed on Windows Terminal Servers, the TS Agent assigns a unique port range to individual users as they log in or log out of a monitored network. The Firepower Management Center uses the unique port to identify individual users in the Firepower System. You can use one TS Agent to monitor user activity on one Windows Terminal Server and send encrypted data to a Firepower Management Center.

The TS Agent does not report failed login attempts. The data gained from the TS Agent can be used for user awareness and user control.

video TS Agent setup video on YouTube.

TS Agent Guidelines

The TS Agent requires a multi-step configuration, and includes the following:

1. A Windows Terminal Server with the TS Agent installed and configured.
2. One or more identity realms targeting the users your server is monitoring.

You install the TS Agent on a Microsoft Windows Terminal Server. For detailed information about the multi-step TS Agent installation and configuration and a complete discussion of the server and Firepower System requirements, see the *Cisco Terminal Services (TS) Agent Guide*.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

Note If the TS Agent monitors the same users as another passive authentication identity source (the user agent or ISE/ISE-PIC), the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and another passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firepower Management Center.

Configure the TS Agent for User Control

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the *Cisco Terminal Services (TS) Agent Guide*.

What to do next:

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2066.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1267.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 374.
- Monitor user activity as discussed in Using Workflows, on page 2294.

Troubleshoot the TS Agent Identity Source

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2009 and Troubleshoot User Control, on page 415.

If you experience issues with the TS Agent-Firepower System integration, check the following:

- You must synchronize the time on your TS Agent server with the time on the Firepower Management Center.
- If the TS Agent monitors the same users as another passive authentication identity source (the User Agent or ISE), the Firepower Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firepower Management Center.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

For complete troubleshooting information, see the *Cisco Terminal Services (TS) Agent Configuration Guide*.

History for TS Agent

Feature	Version	Details
TS Agent for user control.	6.2.0	Feature introduced. Firepower now provides the ability to better identify individual users in shared environments, such as Citrix's Virtual Desktop Infrastructure (VDI), to accurately enforce user-based policy rules on the firewall. Users are identified by ports used. The TS Agent software is updated independently of the Firepower Management Center. For more information, see: • *Cisco Terminal Services (TS) Agent Guide* available on cisco.com • Cisco Firepower Compatibility Guide

CHAPTER 100

Control Users with the User Agent

The following topics discuss how to perform user awareness and user control with the user agent:

The User Agent Identity Source

The Cisco Firepower User Agent is a passive authentication method; it is an authoritative identity source, meaning user information is supplied by a trusted Active Directory server. When integrated with the Firepower System, the user agent monitors users when they log in and out of hosts with Active Directory credentials. The data gained from the User Agent can be used for user awareness and user control.

The user agent associates each user with an IP address, which allows access control rules with user conditions to trigger. You can use one user agent to monitor user activity on up to five Active Directory servers and send encrypted data to up to five Firepower Management Centers.

The User Agent does not report failed login attempts.

Video User agent setup video on YouTube.

End of FMC Support for User Agent

End of support is planned for FMC integration with the Cisco Firepower User Agent (hereafter referred to as *user agent*) in a future release.

We strongly recommend you stop using the user agent and switch to using ISE/ISE-PIC as soon as possible.

You'll benefit from the following features, which are not available in the user agent:

- Support for Microsoft Active Directory up to version 2016
- Gathers authentication data from up to 10 Microsoft Active Directory domain controllers
- Gathers Active Directory authentication data from switches supporting Kerberos SPAN

- Supports passive/active redundancy
- You can upgrade from the ISE-PIC to ISE, adding the Passive Identity Connector node to an existing Cisco ISE cluster.
- Supports KVM, VMware, and Hyper-V
- Tailored to fit your organization with support for 3,000 and 300,000 sessions, depending on licensing

You are eligible for a free ISE-PIC license if you have a current support contract for any of the following:

- Any FMC hardware model
- Virtual FMC v25
- Virtual FMC v300

For the preceding models, request part number **L-FMC-ISE-PIC=**.

Note If you have FMCv2 and FMCv10, you must use the standard ISE-PIC part numbers.

Requirements and Prerequisites for User Agent

Model Support

Any.

Supported Domains

Global

User Roles

- Access Admin
- Network Admin

User Agent Guidelines

The User Agent requires a multi-step configuration that includes the following:

- At least one computer with the user agent installed.
- Connections between a Firepower Management Center and the computers or Active Directory servers with the user agent installed.
- An identity realm configured in each Firepower Management Center that receives user data from a user agent.

For detailed information about the multi-step User Agent configuration and a complete discussion of the server requirements, see the *Cisco Firepower User Agent Configuration Guide*.

Note Make sure the time on your computer or Active Directory server is synchronized with the time on the Firepower Management Center. If the appliances are not synchronized, the system might perform user timeouts at unexpected intervals.

The Firepower Management Center connection not only allows you to retrieve metadata for the users whose logins and logoffs were detected by User Agents, but also is used to specify the users and groups you want to use in access control rules. If the user agent is configured to exclude specific user names, login data for those user names are not reported to the Firepower Management Center. User agent data is stored in the user database and user activity database on the Firepower Management Center.

Note User Agents cannot transmit Active Directory user names ending with the `$` character to the Firepower Management Center. You must remove the final `$` character if you want to monitor these users.

If multiple users are logged into a host using remote sessions, the agent might not detect logins from that host properly. For information about how to prevent this, see the *Cisco Firepower User Agent Configuration Guide*.

Configure the User Agent for User Control

For more information about the User Agent, see The User Agent Identity Source, on page 2055.

Before you begin

- Configure and enable an Active Directory realm for your User Agent connection as described in Create a Realm, on page 1997.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **System** > **Integration**.

Step 3 Click **Identity Sources**.

Step 4 Click **User Agent** for the **Service Type** to enable the User Agent connection.

Note To disable the connection, click **None**.

Step 5 Click **New Agent** to add a new agent.

Step 6 Enter the **Hostname** or **Address** of the computer where you plan to install the agent. You must use an IPv4 address; you cannot configure the Firepower Management Center to connect to a User Agent using an IPv6 address.

Step 7 Click **Add**.

Step 8 To delete a connection, click **Delete** ( ) and confirm that you want to delete it.

What to do next

- Continue User Agent setup as described in the *Cisco Firepower User Agent Configuration Guide*.
- Configure an identity rule as described in Create an Identity Rule, on page 2063.
- Associate the identity policy with an access control policy as discussed in Associating Other Policies with Access Control, on page 1267.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 374.

Related Topics

Troubleshoot the User Agent Identity Source, on page 2058
Access Control Policies, on page 1255

Troubleshoot the User Agent Identity Source

If you experience issues with the User Agent connection, see the *Cisco Firepower User Agent Configuration Guide*.

For related troubleshooting information in this guide, see Troubleshoot Realms and User Downloads, on page 2009 and Troubleshoot User Control, on page 415.

If you experience issues with user data reported by the User Agent, note:

- After the system detects activity from a User Agent user whose data is not yet in the database, the system retrieves information about them from the server. That user's activity is not handled by rules, and is not displayed in the web interface until the system successfully retrieves information about them in a user download.
- If you have Firepower Management Center high availability configured and the primary fails, all logins reported by a User Agent cannot be identified during failover downtime, even if the users were previously seen and downloaded to the Firepower Management Center. The unidentified users are logged as Unknown users on the Firepower Management Center. After the downtime, the Unknown users are re identified and processed according to the rules in your identity policy.
- If the User Agent monitors the same users as the TS Agent, the system prioritizes the TS Agent data. If the TS Agent and the User Agent report identical activity from the same IP address, only the TS Agent data is logged.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

History for the User Agent

Feature	Version	Details
User agent deprecated	6.5	The user agent is deprecated and will be removed in a future release. We strongly recommend you use ISE/ISE-PIC instead of the user agent.
User agent version 2.5	6.5	You can change the default password the user agent uses to authenticate with the FMC. New FMC command: **configure user-agent**
User agent for user control.	—	Feature introduced before Version 6.0. User agent provides login details for Active Directory users and can be used for user awareness and user control.

CHAPTER 101

Create and Manage Identity Policies

The following topics discuss how to create and manage identity rules and identity policies:

About Identity Policies

Identity policies contain identity rules. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication.

With the exception noted in the following paragraphs, you must configure realms and authentication methods you plan to use before you can invoke them in your identity rules:

- You configure realms outside of your identity policy, at **System** > **Integration** > **Realms**. For more information, see Create a Realm, on page 1997.
- You configure the user agent and ISE/ISE-PIC, passive authentication identity sources, at **System** > **Integration** > **Identity Sources**. For more information, see Configure the User Agent for User Control, on page 2057 and Configure ISE/ISE-PIC for User Control, on page 2026.
- You configure the TS Agent, a passive authentication identity source, outside the Firepower System. For more information, see the *Cisco Terminal Services (TS) Agent Guide*.
- You configure captive portal, an active authentication identity source, within the identity policy. For more information, see How to Configure the Captive Portal for User Control, on page 2036.
- You configure Remote Access VPN, an active authentication identity source, in Remote Access VPN policies. For more information, see Remote Access VPN Authentication, on page 878.

After you add multiple identity rules to a single identity policy, order the rules. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles the traffic.

After you configure one or more identity policies, you must associate one identity policy with your access control policy. When traffic on your network matches the conditions in your identity rule, the system associates the traffic with the specified realm and authenticates the users in the traffic using the specified identity source.

If you do not configure an identity policy, the system does not perform user authentication.

Exception to creating an identity policy

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions, on page 417.

Create an Identity Rule

For details about configuration options for identity rules, see Identity Rule Fields, on page 2064.

Before you begin

You must create and enable a realm.

- Create a realm as discussed in Create a Realm, on page 1997.
- Create a directory as discussed in Configure a Realm Directory, on page 2006.
- Download users and groups and enable the realm as discussed in Download Users and Groups, on page 2007.

Step 1 If you haven't done so already, log in to the Firepower Management Center.

Step 2 Click **Policies** > **Access Control** > **Identity** .

Step 3 Click **Edit** ( ) next to the identity policy to which to add the identity rule.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Rule**.

Step 5 Enter a **Name**.

Step 6 Specify whether the rule is **Enabled**.

Step 7 To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.

Step 8 Choose a rule **Action** from the list.

Step 9 Click **Realms & Settings**.

Step 10 Choose a realm for the identity rule from the **Realms** list. You must associate a realm with every identity rule.

The only exception to the realm requirement is implementing user control using only the ISE SGT attribute tag. In this case, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy.

Step 11 If you're configuring captive portal, see How to Configure the Captive Portal for User Control, on page 2036.

Step 12 (Optional) To add conditions to the identity rule, see Rule Condition Types, on page 391.

Step 13 Click **Add**.

Step 14 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 15 Click **Save**.

Identity Rule Fields

Use the following fields to configure identity rules.

Enabled

Choosing this option enables the identity rule in the identity policy. Deselecting this option disables the identity rule.

Action

Specify the type of authentication you want to perform on the users in the specified realm: **Passive Authentication** (default), **Active Authentication**, or **No Authentication**. You must fully configure the authentication method, or *identity source*, before selecting it as the action in an identity rule.

Additionally, if VPN is enabled (configured on at least one managed device), remote access VPN sessions are actively authenticated by VPN. Other sessions use the rule action. This means that, if VPN is enabled, VPN identity determination is performed first for all sessions regardless of the selected action. If a VPN identity is found on the specified realm, this is the identity source used. No additional captive portal active authentication is done, even if selected.

If the VPN identity source is not found, the process continues according to the specified action. You cannot restrict the identity policy to VPN authentication only because if the VPN identity is not found, the rule is applied according to the selected action.

Caution Adding the first or removing the last active authentication rule when SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

For information about which passive and active authentication methods are supported in your version of the Firepower System, see About User Identity Sources, on page 1926.

Realm

The realm containing the users you want to perform the specified **Action** on. You must fully configure a realm before selecting it as the realm in an identity rule.

Note If remote access VPN is enabled and your deployment is using a RADIUS server group for VPN authentication, make sure you specify the realm associated with this RADIUS server group.

Note If you select **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Protocol** for the identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Use active authentication if passive or VPN identity cannot be established

Selecting this option authenticates users using captive portal active authentication if a passive or a VPN authentication fails to identify them. You must configure captive portal active authentication in your identity policy in order to select this option.

If you disable this option, users that do not have a VPN identity or that passive authentication cannot identify are identified as Unknown.

Identify as Special Identities/Guest if authentication cannot identify user

Selecting this option allows users who fail captive portal active authentication the specified number of times times to access your network as a guest. These users appear in the Firepower Management Console identified by their username (if their username exists on the AD or LDAP server) or by **Guest** (if their user name is unknown). Their realm is the realm specified in the identity rule. (By default, the number of failed logins is 3.)

This field is displayed only if you configure **Active Authentication** (that is, captive portal authentication) as the rule **Action**.

Authentication Protocol

The method to use to perform captive portal active authentication. The selections vary depending on the type of realm, LDAP or AD:

- Choose **HTTP Basic** if you want to authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication popup window.

  Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.

- Choose **NTLM** to authenticate users using a NT LAN Manager (NTLM) connection. This selection is available only when you select an AD realm. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication popup window.
- Choose **Kerberos** to authenticate users using a Kerberos connection. This selection is available only when you select an AD realm for a server with secure LDAP (LDAPS) enabled. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication popup window.

Note The **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform Kerberos captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the host name you provided when configuring DNS.

For ASA with FirePOWER Services and Firepower Threat Defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.

- Choose **HTTP Negotiate** to allow the captive portal server to choose between HTTP Basic, Kerberos, or NTLM for the authentication connection. This type is available only when you select an AD realm.

Note The **Realm** you choose must be configured with an **AD Join Username** and **AD Join Password** for **HTTP Negotiate** to choose Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform **HTTP Negotiate** captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN of the device you are using for captive portal must match the hostname you provided when configuring DNS.

For ASA with FirePOWER Services devices, the FQDN is the FQDN of the ASA FirePOWER module.

Create an Identity Policy

Before you begin

An identity policy is required to use users and groups in a realm in access control policies. Create and enable one or more realms as described in Create a Realm, on page 1997.

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions, on page 417.

Step 1 Log in to the Firepower Management Center.

Step 2 Click **Policies** > **Access Control** > **Identity** and click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

Step 5 To add a rule to the policy, click **Add Rule** as described in Create an Identity Rule, on page 2063.

Step 6 To create a rule category, click **Add Category**.

Step 7 To configure captive portal active authentication, click **Active Authentication** as described in Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038.

Step 8 Click **Save** to save the identity policy.

What to do next

- Add rules to your identity policy that specify which users to match and other options; see Create an Identity Rule, on page 2063.
- Associate the identity policy with an access control policy to allow or block selected users from accessing specified resources; see Associating Other Policies with Access Control, on page 1267.
- Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 374.

If you encounter issues, see Troubleshoot User Control, on page 415.

Related Topics

Configure the Captive Portal Part 1: Create an Identity Policy, on page 2038
Captive Portal Fields, on page 2043
Troubleshoot User Control, on page 415

Manage an Identity Rule

Step 1 If you haven't already done so, log in to the Firepower Management Center.

Step 2 Click **Policies** > **Access Control** > **Identity** .

Step 3 Click **Edit** ( ) next to the policy you want to edit. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit an identity rule, click **Edit** ( ) and make changes as described in Create an Identity Policy, on page 2066.

Step 5 To delete an identity rule, click **Delete** ( ).

Step 6 To create a rule category, click **Add Category** and choose the position and the rule.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Manage an Identity Policy

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Step 1 If you haven't done so already, log in to the Firepower Management Center.

Step 2 Click **Policies** > **Access Control** > **Identity** .

Step 3 To delete a policy, click **Delete** ( ). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit a policy, click **Edit** ( ) next to the policy and make changes as described in Create an Identity Policy, on page 2066. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 5 To copy a policy, click **Copy** ( ).

Step 6 To generate a report for the policy, click **Report** ( ) as described in Generating Current Policy Reports, on page 384.

Step 7 To compare policies, see Comparing Policies, on page 383.

CHAPTER 102

Network Discovery Policies

The following topics describe how to create, configure, and manage network discovery policies:

Overview: Network Discovery Policies

The network discovery policy on the Firepower Management Center controls how the system collects data on your organization's network assets and which network segments and ports are monitored.

In a multidomain deployment, each leaf domain has an independent network discovery policy. Network discovery policy rules and other settings cannot be shared, inherited, or copied between domains. Whenever you create a new domain, the system creates a network discovery policy for the new domain, using default settings. You must explicitly apply any desired customizations to the new policy.

Discovery rules within the policy specify which networks and ports the Firepower System monitors to generate discovery data based on network data in traffic, and the zones to which the policy is deployed. Within a rule, you can configure whether hosts, applications, and non-authoritative users are discovered. You can create rules to exclude networks and zones from discovery. You can configure discovery of data from NetFlow exporters and restrict the protocols for traffic where user data is discovered on your network.

The network discovery policy has a single default rule in place, configured to discover applications from all observed traffic. The rule does not exclude any networks, zones, or ports, host and user discovery is not configured, and the rule is not configured to monitor a NetFlow exporter. This policy is deployed by default to any managed devices when they are registered to the Firepower Management Center. To begin collecting host or user data, you must add or modify discovery rules and re-deploy the policy to a device.

If you want to adjust the scope of network discovery, you can create additional discovery rules and modify or remove the default rule.

Remember that the access control policy for each managed device defines the traffic that you permit for that device and, therefore, the traffic you can monitor with network discovery. If you block certain traffic using access control, the system cannot examine that traffic for host, user, or application activity. For example, if an access control policy blocks access to social networking applications, the system cannot provide any discovery data on those applications.

If you enable traffic-based user detection in your discovery rules, you can detect non-authoritative users through user login activity in traffic over a set of application protocols. You can disable discovery in particular protocols across all rules if needed. Disabling some protocols can help avoid reaching the user limit associated with your Firepower Management Center model, reserving available user count for users from the other protocols.

Advanced network discovery settings allow you to manage what data is logged, how discovery data is stored, what indications of compromise (IOC) rules are active, what vulnerability mappings are used for impact assessment, and what happens when sources offer conflicting discovery data. You can also add sources for host input and NetFlow exporters to monitor.

Requirements and Prerequisites for Network Discovery Policies

Model Support

Any.

Supported Domains

Leaf

User Roles

- Discovery Admin

Network Discovery Customization

The information about your network traffic collected by the Firepower System is most valuable to you when the system can correlate this information to identify the hosts on your network that are most vulnerable and most important.

As an example, if you have several devices on your network running a customized version of SuSE Linux, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for SuSE Linux, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for SuSE Linux in the fingerprint to associate that list with each host that matches the fingerprint.

The system also allows you to input host data from third-party systems directly into the network map, using the host input feature. However, third-party operating system or application data does not automatically map to vulnerability information. If you want to see vulnerabilities and perform impact correlation for hosts using third-party operating system, server, and application protocol data, you must map the vendor and version information from the third-party system to the vendor and version listed in the vulnerability database (VDB). You also may want to maintain the host input data on an ongoing basis. Note that even if you map application data to Firepower System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

If the system cannot identify application protocols running on hosts on your network, you can create user-defined application protocol detectors that allow the system to identify the applications based on a port

or a pattern. You can also import, activate, and deactivate certain application detectors to further customize the application detection capability of the Firepower System.

You can also replace detection of operating system and application data using scan results from the Nmap active scanner or augment the vulnerability lists with third-party vulnerabilities. The system may reconcile data from multiple sources to determine the identity for an application.

Configuring the Network Discovery Policy

In a multidomain deployment, each domain has a separate network discovery policy. If your user account can manage multiple domains, switch to the leaf domain where you want to configure the policy.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Configure the following components of your policy:

- Discovery rules — See Configuring Network Discovery Rules, on page 2072.
- Traffic-based detection for users — See Configuring Traffic-Based User Detection, on page 2079.
- Advanced network discovery options — See Configuring Advanced Network Discovery Options, on page 2080.
- Custom operating system definitions (fingerprints) — See Creating a Custom Fingerprint for Clients, on page 1942 and Creating a Custom Fingerprint for Servers, on page 1944.

Network Discovery Rules

Network discovery rules allow you to tailor the information discovered for your network map to include only the specific data you want. Rules in your network discovery policy are evaluated sequentially. You can create rules with overlapping monitoring criteria, but doing so may affect your system performance.

When you exclude a host or a network from monitoring, the host or network does not appear in the network map and no events are reported for it. However, when the host discovery rules for the local IP are disabled, the detection engine instances are impacted by a higher processing load, as it builds data from each flow afresh rather than using the existing host data.

We recommend that you exclude load balancers (or specific ports on load balancers) and NAT devices from monitoring. These devices may create excessive and misleading events, filling the database and overloading the Firepower Management Center. For example, a monitored NAT device might exhibit multiple updates of its operating system in a short period of time. If you know the IP addresses of your load balancers and NAT devices, you can exclude them from monitoring.

Tip The system can identify many load balancers and NAT devices by examining your network traffic.

In addition, if you need to create a custom server fingerprint, you should temporarily exclude from monitoring the IP address that you are using to communicate with the host you are fingerprinting. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by

that IP address. After you create the fingerprint, you can configure your policy to monitor that IP address again.

Cisco also recommends that you **not** monitor the same network segment with NetFlow exporters and Firepower System managed devices. Although ideally you should configure your network discovery policy with non-overlapping rules, the system does drop duplicate connection logs generated by managed devices. However, you **cannot** drop duplicate connection logs for connections detected by both a managed device and a NetFlow exporter.

Configuring Network Discovery Rules

You can configure discovery rules to tailor the discovery of host and application data to your needs.

Before you begin

- Make sure you are logging connections for the traffic where you want to discover network data; see Best Practices for Connection Logging, on page 2362.
- If you want to collect exported NetFlow records, add a NetFlow Exporter as described in Adding NetFlow Exporters to a Network Discovery Policy, on page 2085.
- If you will want to view discovery performance graphs, you must enable hosts, users, and applications in your discovery rule. Note that this may impact system performance.

Tip In most cases, Cisco suggests restricting discovery to the addresses in RFC 1918.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Add Rule**.

Step 3 Set the **Action** for the rule as described in Actions and Discovered Assets, on page 2073.

Step 4 Set optional discovery parameters:

- Restrict the rule action to specific networks; see Restricting the Monitored Network, on page 2074.
- Restrict the rule action to traffic in specific zones; see Configuring Zones in Network Discovery Rules, on page 2077.
- Exclude ports from monitoring; see Excluding Ports in Network Discovery Rules, on page 2076.
- Configure the rule for NetFlow data discovery; see Configuring Rules for NetFlow Data Discovery, on page 2074.

Step 5 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Actions and Discovered Assets

When you configure a discovery rule, you must select an action for the rule. The effect of that action depends on whether you are using the rule to discover data from a managed device or from a NetFlow exporter.

The following table describes what assets are discovered by rules with the specified action settings in those two scenarios.

Table 244: Discovery Rule Actions

Action	Option	Managed Device	NetFlow Exporter
Exclude	--	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.
Discover	Hosts	Adds hosts to the network map based on discovery events. (Optional, unless user discovery is enabled, then required.)	Adds hosts to the network map and logs connections based on NetFlow records. (Required)
Discover	Applications	Adds applications to the network map based on application detectors. Note that you cannot discover hosts or users in a rule without also discovering applications. (Required)	Adds application protocols to the network map based on NetFlow records and the port-application protocol correlation in `/etc/sf/services`. (Optional)
Discover	Users	Adds users to the users table and logs user activity based on traffic-based detection on the user protocols configured in the network discovery policy. (Optional)	n/a
Log NetFlow Connections	--	n/a	Logs NetFlow connections only. Does not discover hosts or applications.

If you want the rule to monitor managed device traffic, application logging is required. If you want the rule to monitor users, host logging is required. If you want the rule to monitor exported NetFlow records, you cannot configure it to log users, and logging applications is optional.

Note The system detects connections in exported NetFlow records based on the **Action** settings in the network discovery policy. The system detects connections in managed device traffic based on access control policy settings.

Monitored Networks

A discovery rule causes discovery of monitored assets only in traffic to and from hosts in the specified networks. For a discovery rule, discovery occurs for connections that have at least one IP address within the networks specified, with events generated only for IP addresses within the networks to monitor. The default discovery rule discovers applications from all observed traffic (`0.0.0.0/0` for all IPv4 traffic, and `::/0` for all IPv6 traffic).

If you configure a rule to handle NetFlow discovery and log only connections data, the system also logs connections to and from IP addresses in the specified networks. Note that network discovery rules provide the only way to log NetFlow network connections.

You can also use network object or object groups to specify the networks to monitor.

Restricting the Monitored Network

Every discovery rule must include at least one network.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Add Rule**.

Step 3 Click **Networks**, if it is not already open.

Step 4 Optionally, add network objects to the Available Networks list as described in Creating Network Objects During Discovery Rule Configuration, on page 2075.

Note If you modify a network object used in the network discovery policy, the changes do not take effect for discovery until you deploy the configuration changes.

Step 5 Specify a network:

- Choose a network from the **Available Networks** list.

  Tip If the network does not immediately appear on the list, click **Reload** ( ).

- Enter the IP address into the text box below the Available Networks label.

Step 6 Click **Add**.

Step 7 Optionally, repeat the previous two steps to add additional networks.

Step 8 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Configuring Rules for NetFlow Data Discovery

The Firepower System can use data from NetFlow exporters to generate connection and discovery events, and to add host and application data to the network map.

If you choose a NetFlow exporter in a discovery rule, the rule is limited to discovery of NetFlow data for the specified networks. Choose the NetFlow device to monitor before you configure other aspects of rule behavior, as the available rule actions change when you choose a NetFlow device. You cannot configure port exclusions for monitoring NetFlow exporters.

Before you begin

- Add NetFlow-enabled devices to the network discovery policy; see Adding NetFlow Exporters to a Network Discovery Policy, on page 2085.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Add Rule**.

Step 3 Choose **NetFlow Device**.

Step 4 From the **Netflow Device** drop-down list, choose the IP address of the NetFlow exporter to be monitored.

Step 5 Specify the type of NetFlow data you want the Firepower System managed device to collect:

- Connection only — Choose `Log NetFlow Connections` from the **Action** drop-down list.
- Host, Application, and Connection — Choose `Discover` from the **Action** drop-down list. The system automatically checks the **Hosts** check box and enables collection of connection data. Optionally, you can check the **Application** check box to collect application data.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Creating Network Objects During Discovery Rule Configuration

You can add new network objects to the list of available networks that appears in a discovery rule by adding them to the list of reusable network objects and groups.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 In **Networks**, click **Add Rule**.

Step 3 Click **Add** () next to **Available Networks**.

Step 4 Create a network object as described in Creating Network Objects, on page 434.

Step 5 Finish adding the network discovery rule as described in Configuring Network Discovery Rules, on page 2072.

Port Exclusions

Just as you can exclude hosts from monitoring, you can exclude specific ports from monitoring. For example:

- Load balancers can report multiple applications on the same port in a short period of time. You can configure your network discovery rules so that they exclude that port from monitoring, such as excluding port 80 on a load balancer that handles a web farm.
- Your organization may use a custom client that uses a specific range of ports. If the traffic from this client generates excessive and misleading events, you can exclude those ports from monitoring. Similarly, you may decide that you do not want to monitor DNS traffic. In that case, you could configure your rules so that your discovery policy does not monitor port 53.

When adding ports to exclude, you can decide whether to use a reusable port object from the Available Ports list, add ports directly to the source or destination exclusion lists, or create a new reusable port and then move it into the exclusion lists.

Note You cannot exclude ports in rules handling NetFlow data discovery.

Excluding Ports in Network Discovery Rules

You cannot exclude ports in rules handling NetFlow data discovery.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 Optionally, add port objects to the Available Ports list as described in Creating Port Objects During Discovery Rule Configuration, on page 2076.

Step 5 Exclude specific source ports from monitoring, using either of the following methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Source**.
- To exclude traffic from a specific source port without adding a port object, under the **Selected Source Ports** list, choose a **Protocol**, enter a **Port** number (a value from 1 to 65535), and click **Add**.

Step 6 Exclude specific destination ports from monitoring, using either of the following methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Destination**.
- To exclude traffic from a specific destination port without adding a port object, under the **Selected Destination Ports** list, choose a **Protocol**, enter a **Port** number, and click **Add**.

Step 7 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Creating Port Objects During Discovery Rule Configuration

You can add new port objects to the list of available ports that appears in a discovery rule by adding them to the list of reusable port objects and groups that can be used anywhere in the Firepower System.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 In Networks, click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 To add a port to the Available Ports list, click **Add** ( ).

Step 5 Supply a **Name**.

Step 6 In the **Protocol** field, specify the protocol of the traffic you want to exclude.

Step 7 In the **Port** field, enter the ports you want to exclude from monitoring.

You can specify a single port, a range of ports using the dash (-), or a comma-separated list of ports and port ranges. Allowed port values are from 1 to 65535.

Step 8 Click **Save**.

Step 9 If the port does not immediately appear on the list, click **Refresh**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Zones in Network Discovery Rules

To improve performance, discovery rules can be configured so that the zones in the rule include the sensing interfaces on your managed devices that are physically connected to the networks-to-monitor in the rule.

Unfortunately, you may not always be kept informed of network configuration changes. A network administrator may modify a network configuration through routing or host changes without informing you, which may make it challenging to stay on top of proper network discovery policy configurations. If you do not know how the sensing interfaces on your managed devices are physically connected to your network, leave the zone configuration as the default. This default causes the system to deploy the discovery rule to all zones in your deployment. (If no zones are excluded, the system deploy the discovery policy to all zones.)

Configuring Zones in Network Discovery Rules

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Add Rule**.

Step 3 Click **Zones**.

Step 4 Choose a zone or zones from the **Available Zones** list.

Step 5 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

The Traffic-Based Detection Identity Source

Traffic-based detection is the only non-authoritative identity source supported by the Firepower System. When configured, managed devices detect LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), FTP, HTTP, MDNS, and SMTP logins on the networks you specify. The data gained from traffic-based detection can be used only

for user awareness. Unlike authoritative identity sources, you configure traffic-based detection in your network discovery policy as described in Configuring Traffic-Based User Detection, on page 2079.

Note the following limitations:

- Traffic-based detection interprets only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications using protocols such as SSL or TLS.
- Traffic-based detection detects AIM logins using the OSCAR protocol only. They cannot detect AIM logins using TOC2.
- Traffic-based detection cannot restrict SMTP logging. This is because users are not added to the database based on SMTP logins; although the system detects SMTP logins, the logins are not recorded unless there is already a user with a matching email address in the database.

Traffic-based detection also records failed login attempts. A failed login attempt does not add a new user to the list of users in the database. The user activity type for detected failed login activity detected by traffic-based detection is **Failed User Login**.

Note The system cannot distinguish between failed and successful HTTP logins. To see HTTP user information, you must enable **Capture Failed Login Attempts** in the traffic-based detection configuration.

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

Traffic-Based Detection Data

When a device detects a login using traffic-based detection, it sends the following information to the Firepower Management Center to be logged as user activity:

- the user name identified in the login
- the time of the login
- the IP address involved in the login, which can be the IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for HTTP, MDNS, FTP, SMTP and Oracle logins), or the session originator (for SIP logins)
- the user's email address (for POP3, IMAP, and SMTP logins)
- the name of the device that detected the login

If the user was previously detected, the Firepower Management Center updates that user's login history. Note that the Firepower Management Center can use the email addresses in POP3 and IMAP logins to correlate with LDAP users. This means that, for example, if the Firepower Management Center detects a new IMAP login, and the email address in the IMAP login matches that for an existing LDAP user, the IMAP login does not create a new user; rather, it updates the LDAP user's history.

If the user was previously undetected, the Firepower Management Center adds the user to the users database. Unique AIM, SIP, and Oracle logins always create new user records, because there is no data in those login events that the Firepower Management Center can correlate with other login types.

The Firepower Management Center does **not** log user activity or user identities in the following cases:

- if you configured the network discovery policy to ignore that login type
- if a managed device detects an SMTP login, but the users database does not contain a previously detected LDAP, POP3, or IMAP user with a matching email address

The user data is added to the users table.

Traffic-Based Detection Strategies

You can restrict the protocols where user activity is discovered to reduce the total number of detected users so you can focus on users likely to provide the most complete user information. Limiting protocol detection helps minimize user name clutter and preserve storage space on your Firepower Management Center.

Consider the following when selecting traffic-based detection protocols:

- Obtaining user names through protocols such as AIM, POP3, and IMAP may introduce user names not relevant to your organization due to network access from contractors, visitors, and other guests.
- AIM, Oracle, and SIP logins may create extraneous user records. This occurs because these login types are not associated with any of the user metadata that the system obtains from an LDAP server, nor are they associated with any of the information contained in the other types of login that your managed devices detect. Therefore, the Firepower Management Center cannot correlate these users with other types of users.

Configuring Traffic-Based User Detection

When you enable traffic-based user detection in a network discovery rule, host discovery is automatically enabled. For more information about traffic-based detection, see The Traffic-Based Detection Identity Source, on page 2077.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Users**.

Step 3 Click **Edit** ( ).

Step 4 Check the check boxes for protocols where you want to detect logins or clear check boxes for protocols where you do not want to detect logins.

Step 5 Optionally, to record failed login attempts detected in LDAP, POP3, FTP, or IMAP traffic, or to capture user information for HTTP logins, enable **Capture Failed Login Attempts**.

Step 6 Click **Save**.

What to do next

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information.

- Configure network discovery rules to discover users as described in Configuring Network Discovery Rules, on page 2072.
- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Configuring Advanced Network Discovery Options

The Advanced of the network discovery policy allows you to configure policy-wide settings for what events are detected, how long discovery data is retained and how often it is updated, what vulnerability mappings are used for impact correlation, and how operating system and server identity conflicts are resolved. In addition, you can add host input sources and NetFlow exporters to allow import of data from other sources.

Note Database event limits for discovery and user activity events are set in system configuration.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) or **Add** ( ) next to the setting you want to modify:

- Data Storage Settings — Update the settings as described in Configuring Network Discovery Data Storage, on page 2087.
- Event Logging Settings — Update the settings as described in Configuring Network Discovery Event Logging, on page 2087.
- General Settings — Update the settings as described in Configuring Network Discovery General Settings, on page 2081.
- Identity Conflict Settings — Update the settings as described in Configuring Network Discovery Identity Conflict Resolution, on page 2082.
- Indications of Compromise Settings — Update the settings as described in Enabling Indications of Compromise Rules, on page 2084.
- NetFlow Exporters — Update the settings as described in Adding NetFlow Exporters to a Network Discovery Policy, on page 2085.
- OS and Server Identity Sources — Update the settings as described in Adding Network Discovery OS and Server Identity Sources, on page 2088.
- Vulnerabilities to use for Impact Assessment — Update the settings as described in Enabling Network Discovery Vulnerability Impact Assessment, on page 2083.

Step 4 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Related Topics

Database Event Limits, on page 1019

Network Discovery General Settings

The general settings control how often the system updates network maps and whether server banners are captured during discovery.

Capture Banners

Select this check box if you want the system to store header information from network traffic that advertises server vendors and versions ("banners"). This information can provide additional context to the information gathered. You can access server banners collected for hosts by accessing server details.

Update Interval

The interval at which the system updates information (such as when any of a host's IP addresses was last seen, when an application was used, or the number of hits for an application). The default setting is 3600 seconds (1 hour).

Note that setting a lower interval for update timeouts provides more accurate information in the host display, but generates more network events.

Configuring Network Discovery General Settings

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) next to **General Settings**.

Step 4 Update the settings as described in Network Discovery General Settings, on page 2081.

Step 5 Click **Save** to save the general settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Network Discovery Identity Conflict Settings

The system determines which operating system and applications are running on a host by matching fingerprints for operating systems and servers against patterns in traffic. To provide the most reliable operating system and server identity information, the system collates fingerprint information from several sources.

The system uses all passive data to derive operating system identities and assign a confidence value.

By default, unless there is an identity conflict, identity data added by a scanner or third-party application overrides identity data detected by the Firepower System. You can use the Identity Sources settings to rank scanner and third-party application fingerprint sources by priority. The system retains one identity for each source, but only data from the highest priority third-party application or scanner source is used as the current identity. Note, however, that user input data overrides scanner and third-party application data regardless of priority.

An identity conflict occurs when the system detects an identity that conflicts with an existing identity that came from either the active scanner or third-party application sources listed in the Identity Sources settings or from a Firepower System user. By default, identity conflicts are not automatically resolved and you must resolve them through the host profile or by rescanning the host or re-adding new identity data to override the passive identity. However, you can set your system to automatically resolve the conflict by keeping either the passive identity or the active identity.

Generate Identity Conflict Event

Specifies whether the system generates an event when an identity conflict occurs.

Automatically Resolve Conflicts

From the **Automatically Resolve Conflicts** drop-down list, choose one of the following:

- **Disabled** if you want to force manual conflict resolution of identity conflicts
- **Identity** if you want to the system to use the passive fingerprint when an identity conflict occurs
- **Keep Active** if you want the system to use the current identity from the highest priority active source when an identity conflict occurs

Configuring Network Discovery Identity Conflict Resolution

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Identity Conflict Settings**.

Step 4 Update the settings in the Edit Identity Conflict Settings pop-up window as described in Network Discovery Identity Conflict Settings, on page 2082.

Step 5 Click **Save** to save the identity conflict settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Network Discovery Vulnerability Impact Assessment Options

You can configure how the Firepower System performs impact correlation with intrusion events. Your choices are as follows:

- Check the **Use Network Discovery Vulnerability Mappings** check box if you want to use system-based vulnerability information to perform impact correlation.
- Check the **Use Third-Party Vulnerability Mappings** check box if you want to use third-party vulnerability references to perform impact correlation. For more information, see the *Firepower System Host Input API Guide*.

You can check either or both of the check boxes. If the system generates an intrusion event and the host involved in the event has servers or an operating system with vulnerabilities in the selected vulnerability mapping sets, the intrusion event is marked with the Vulnerable (level 1: red) impact icon. For any servers which do not have vendor or version information, note that you need to enable vulnerability mapping in the Firepower Management Center configuration.

If you clear both check boxes, intrusion events will **never** be marked with the Vulnerable (level 1: red) impact icon.

Mapping Third-Party Vulnerabilities, on page 1950
Mapping Vulnerabilities for Servers, on page 1056

Enabling Network Discovery Vulnerability Impact Assessment

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Vulnerabilities to use for Impact Assessment**.

Step 4 Update the settings in the Edit Vulnerability Settings pop-up window as described in Network Discovery Vulnerability Impact Assessment Options, on page 2083.

Step 5 Click **Save** to save the vulnerability settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Indications of Compromise

The Firepower System uses IOC rules in the network discovery policy to identify a host as likely to be compromised by malicious means. When a host meets the conditions specified in these system-provided rules, the system tags it with an *indication of compromise* (IOC). The related rules are known as *IOC rules*. Each IOC rule corresponds to one type of IOC tag. The *IOC tags* specify the nature of the likely compromise.

The Firepower Management Center can tag the host and user involved when one of the following things occurs:

- The system correlates data gathered about your monitored network and its traffic, using intrusion, connection, Security Intelligence, and file or malware events, and determines that a potential IOC has occurred.
- The Firepower Management Center can import IOC data from your AMP for Endpoints deployments via the AMP cloud. Because this data examines activity on a host itself—such as actions taken by or on individual programs—it can provide insights into possible threats that network-only data cannot. For your convenience, the Firepower Management Center automatically obtains any new IOC tags that Cisco develops from the AMP cloud.

To configure this feature, see Enabling Indications of Compromise Rules, on page 2084.

You can also write correlation rules against host IOC data and compliance white lists that account for IOC-tagged hosts.

To investigate and work with tagged IOCs, see Indications of Compromise Data, on page 2529 and its subtopics.

Enabling Indications of Compromise Rules

For your system to detect and tag indications of compromise (IOC), you must first activate at least one IOC rule in your network discovery policy. Each IOC rule corresponds to one type of IOC tag, and all IOC rules are predefined by Cisco; you cannot create original rules. You can enable any or all rules, depending on the needs of your network and organization. For example, if hosts using software such as Microsoft Excel never appear on your monitored network, you may decide not to enable the IOC tags that pertain to Excel-based threats.

Tip To disable IOC rules for individual hosts or their associated users, see Editing Indication of Compromise Rule States for a Single Host or User, on page 2532.

Before you begin

Because IOC rules trigger based on data provided by other components of the Firepower System and by AMP for Endpoints, those components must be correctly licensed and configured for IOC rules to set IOC tags. Enable the Firepower System features associated with the IOC rules you will enable, such as intrusion detection and prevention (IPS) and Advanced Malware Protection (AMP). If an IOC rule's associated feature is not enabled, no relevant data is collected and the rule cannot trigger.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) next to **Indications of Compromise Settings**.

Step 4 To toggle the entire IOC feature off or on, click the slider next to **Enable IOC**.

Step 5 To globally enable or disable individual IOC rules, click the slider in the rule's **Enabled** column.

Step 6 Click **Save** to save your IOC rule settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Adding NetFlow Exporters to a Network Discovery Policy

Before you begin

- Configure the NetFlow exporters you plan to use as described in Netflow Data in the Firepower System, on page 1921.
- Review the other NetFlow prerequisites described in Requirements for Using NetFlow Data, on page 1922.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Add** ( ) next to **NetFlow Devices**.

Step 4 In the **IP Address** field, enter the IP address of the network device from which you want the managed device to collect NetFlow data.

Step 5 Optionally:

- Repeat the previous two steps to add additional NetFlow exporters.
- Remove a NetFlow exporter by clicking **Delete** ( ). Keep in mind that if you use a NetFlow exporter in a discovery rule, you must delete the rule before you can delete the device from the Advanced page.

Step 6 Click **Save**.

What to do next

- Configure a network discovery rule to monitor NetFlow traffic as described in Configuring Network Discovery Rules, on page 2072.
- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Network Discovery Data Storage Settings

Discovery data storage settings include the host limit and timeout settings.

When Host Limit Reached

The number of hosts a Firepower Management Center can monitor, and therefore store in the network map, depends on its model. The **When Host Limit Reached** option controls what happens when you detect a new host after you reach the host limit. You can:

Drop hosts

The system drops the host that has remained inactive for the longest time, then adds the new host. This is the default setting.

Don't insert new hosts

The system does not track any newly discovered hosts. The system only tracks new hosts after the host count drops below the limit, such as after an administrator increases the domain's host limit or manually deletes hosts from the network map, or if the system identifies hosts as timed-out due to inactivity.

In a multidomain deployment, leaf domains share the available pool of monitored hosts. To ensure that each leaf domain can populate its network map, you can set host limits at any subdomain level in the domain's properties. Because each leaf domain has its own network discovery policy, each leaf domain governs its own behavior when the system discovers a new host, as described in the following table.

Table 245: Reaching the Host Limit with Multitenancy

Setting	Domain Host Limit Set?	Domain Host Limit Reached	Ancestor Domain Host Limit Reached
Drop hosts	yes	Drops oldest host in the constrained domain.	Drops the oldest host among all descendant leaf domains configured to drop hosts. If no host can be dropped, does not add the host.
	no	n/a	Drops the oldest host among all descendant leaf domains configured to drop hosts and that share the general pool.
Don't insert new hosts	yes or no	Does not add the host.	Does not add the host.

Host Timeout

The amount of time that passes, in minutes, before the system drops a host from the network map due to inactivity. The default setting is 10080 minutes (one week). Individual host IP and MAC addresses can time out individually, but a host does not disappear from the network map unless all its associated addresses time out.

To avoid premature timeout of hosts, make sure that the host timeout value is longer than the update interval in the network discovery policy general settings.

Server Timeout

The amount of time that passes, in minutes, before the system drops a server from the network map due to inactivity. The default setting is 10080 minutes (one week).

To avoid premature timeout of servers, make sure that the service timeout value is longer than the update interval in the network discovery policy general settings.

Client Application Timeout

The amount of time that passes, in minutes, before the system drops a client from the network map due to inactivity. The default setting is 10080 minutes (one week).

Make sure that the client timeout value is longer than the update interval in the network discovery policy general settings.

Domain Properties, on page 365

Configuring Network Discovery Data Storage

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Data Storage Settings**.

Step 4 Update the settings in the Data Storage Settings dialog as described in Network Discovery Data Storage Settings, on page 2085.

Step 5 Click **Save** to save the data storage settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Configuring Network Discovery Event Logging

The Event Logging Settings control whether discovery and host input events are logged. If you do not log an event, you cannot retrieve it in event views or use it to trigger correlation rules.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Event Logging Settings**.

Step 4 Check or clear the check boxes next to the discovery and host input event types you want to log in the database, described in Discovery Event Types, on page 2514 and Host Input Event Types, on page 2518.

Step 5 Click **Save** to save the event logging settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Adding Network Discovery OS and Server Identity Sources

In Advanced of the network discovery policy, you can add new active sources or change the priority or timeout settings for existing sources.

Adding a scanner to this page does not add the full integration capabilities that exist for the Nmap scanners, but does allow integration of imported third-party application or scan results.

If you import data from a third-party application or scanner, make sure that you map vulnerabilities from the source to the vulnerabilities detected in your network.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) next to **OS and Server Identity Sources**.

Step 4 To add a new source, click **Add Source**.

Step 5 Enter a **Name**.

Step 6 Choose the input source **Type** from the drop-down list:

- Choose **Scanner** if you plan to import scan results using the AddScanResult function.
- Choose **Application** if you do not plan to import scan results.

Step 7 To indicate the duration of time that should elapse between the addition of an identity to the network map by this source and the deletion of that identity, choose **Hours**, **Days**, or **Weeks** from the **Timeout** drop-down list and enter the appropriate duration.

Step 8 Optionally:

- To promote a source and cause the operating system and application identities to be used in favor of sources below it in the list, choose the source and click the up arrow.
- To demote a source and cause the operating system and application identities to be used only if there are no identities provided by sources above it in the list, choose the source and click the down arrow.
- To delete a source, click **Delete** ( ) next to the source.

Step 9 Click **Save** to save the identity source settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Mapping Third-Party Vulnerabilities, on page 1950

Troubleshooting Your Network Discovery Strategy

Before you make any changes to the system's default detection capabilities, you should analyze what hosts are not being identified correctly and why, so you can decide what solution to implement.

Are Your Managed Devices Correctly Placed?

If network devices such as load balancers, proxy servers, or NAT devices reside between the managed device and the unidentified or misidentified host, place a managed device closer to the misidentified host rather than using custom fingerprinting. Cisco does not recommend using custom fingerprinting in this scenario.

Do Unidentified Operating Systems Have a Unique TCP Stack?

If the system misidentifies a host, you should investigate why the host is misidentified to help you decide between creating and activating a custom fingerprint or substituting Nmap or host input data for discovery data.

Caution If you encounter misidentified hosts, contact your support representative before creating custom fingerprints.

If a host is running an operating system that is not detected by the system by default and does not share identifying TCP stack characteristics with existing detected operating systems, you should create a custom fingerprint.

For example, if you have a customized version of Linux with a unique TCP stack that the system cannot identify, you would benefit from creating a custom fingerprint, which allows the system to identify the host and continuing monitoring it, rather than using scan results or third-party data, which require you to actively update the data yourself on an ongoing basis.

Note that many open source Linux distributions use the same kernel, and as such, the system identifies them using the Linux kernel name. If you create a custom fingerprint for a Red Hat Linux system, you may see other operating systems (such as Debian Linux, Mandrake Linux, Knoppix, and so on) identified as Red Hat Linux, because the same fingerprint matches multiple Linux distributions.

You should not use a fingerprint in every situation. For example, a modification may have been made to a host's TCP stack so that it resembles or is identical to another operating system. For example, an Apple Mac OS X host is altered, making its fingerprint identical to a Linux 2.4 host, causing the system to identify it as Linux 2.4 instead of Mac OS X. If you create a custom fingerprint for the Mac OS X host, it may cause all legitimate Linux 2.4 hosts to be erroneously identified as Mac OS X hosts. In this case, if Nmap correctly identifies the host, you could schedule regular Nmap scans for that host.

If you import data from a third-party system using host input, you must map the vendor, product, and version strings that the third party uses to describe servers and application protocols to the Cisco definitions for those products. Note that even if you map application data to Firepower System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

The system may reconcile data from multiple sources to determine the current identity for an operating system or application.

For Nmap data, you can schedule regular Nmap scans. For host input data, you can regularly run the Perl script for the import or the command line utility. However, note that active scan data and host input data may not be updated with the frequency of discovery data.

Can the Firepower System Identify All Applications?

If a host is correctly identified by the system but has unidentified applications, you can create a user-defined detector to provide the system with port and pattern matching information to help identify the application.

Have You Applied Patches that Fix Vulnerabilities?

If the system correctly identifies a host but does not reflect applied fixes, you can use the host input feature to import patch information. When you import patch information, you must map the fix name to a fix in the database.

Do You Want to Track Third-Party Vulnerabilities?

If you have vulnerability information from a third-party system that you want to use for impact correlation, you can map the third-party vulnerability identifiers for servers and application protocols to vulnerability identifiers in the Cisco database and then import the vulnerabilities using the host input feature. For more information on using the host input feature, see the *Firepower System Host Input API Guide*. Note that even if you map application data to Firepower System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

PART XXI

Correlation and Compliance

CHAPTER 103

Compliance White Lists

The following topics describe how to configure compliance white lists before you add them to correlation policies.

Introduction to Compliance White Lists

A *compliance white list*, sometimes abbreviated as a *white list*, is a set of criteria that specifies which operating systems, applications (web and client), and protocols are allowed on hosts on your network. The system generates an event (violation) if a host is not on this list.

A compliance white list has two main components:

- *Targets* are the hosts you select for compliance evaluation. You can evaluate all or some monitored hosts, constraining by subnet, VLAN, and host attribute. In a multidomain deployment, you can target domains and subnets within or across domains.
- *Host profiles* specify the compliance criteria for the targets. The global host profile is operating system agnostic. You can also configure operating-system specific host profiles, either unique to one white list or shared across multiple white lists.

The Cisco Talos Intelligence Group (Talos) provides a default white list with recommended settings. You can also create custom white lists. A simple custom list might allow only hosts running a certain operating system. A more complex list might allow all operating systems, but specify which operating system a host must use to run a certain application protocol on a specific port.

Note The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923. This limitation may affect the way you build compliance white lists.

Implementing Compliance White Lists

To implement white lists, add the list to an active correlation policy. The system evaluates the targets and assigns every host a corresponding attribute:

- Compliant — The host does not violate the list.
- Non-Compliant — The host violates the list.
- Not Evaluated — The host is not a target of the list, the host is currently being evaluated, or the system has insufficient information to determine whether the host is in compliance.

Note To delete the host attribute, delete its corresponding white list. Deactivating, deleting, or removing a white list from a correlation policy does **not** delete the host attribute, nor does it change the attribute's value for each host.

After its initial evaluation, the system generates a *white list event* whenever a monitored host goes out of compliance with an active white list; it also records a *white list violation*.

You can use workflows, dashboards, and network maps to monitor system-wide compliance activity and determine when and how an individual host violates your white lists. You can also automatically respond to such violations with remediations and alerts.

Example: Restricting HTTP to Web Servers

Your security policy states that only web servers may run HTTP. You create a white list that evaluates your entire network, excluding your web farm, to determine which hosts are running HTTP.

Using the network map and the dashboard, you can obtain an at-a-glance summary of the compliance of your network. In just a few seconds, you can determine exactly which hosts in your organization are running HTTP in violation of your policy, and take appropriate action.

Then, using the correlation feature, you can configure the system to alert you whenever a host that is not in your web farm starts running HTTP.

Related Topics

Configuring Correlation Policies, on page 2109

Compliance White List Target Networks

A *target network* specifies the hosts you want to evaluate for compliance. A white list can have more than one target network, and it evaluates hosts that meet the criteria of any of its targets.

Initially, you constrain a target network by IP address or range. In multidomain deployments, the initial constraints also include a domain.

The system-provided default white list targets all monitored hosts: 0.0.0.0/0 and ::/0. In a multidomain deployment, the default white list is constrained to (and only available in) the Global domain.

If you modify a target network or a host so that the host is no longer a valid target for the white list, the host is no longer evaluated by the list and is considered neither compliant nor non-compliant.

Surveying and Refining Target Networks

When you add a target network to a white list, the system prompts you to survey the network map to help you characterize compliant hosts. The survey adds a target to the white list that represents the hosts you surveyed.

You can survey a subnet or individual host. In a multidomain deployment, you can survey an entire domain, or you can survey across domains. Surveying an ancestor domain causes the system to survey that domain's descendants.

In addition to the added target, the survey also populates the white list with one host profile for each operating system detected in the survey. These host profiles allow all the clients, application protocols, web applications, and protocols that the system has detected on the applicable operating systems.

After you survey a target network (or skip the survey), refine the target. You can exclude hosts by IP address, or constrain target networks by host attribute or VLAN.

Targeting Domains with Compliance White Lists

In a multidomain deployment, domains and target networks are closely linked.

- Leaf-domain administrators can create white lists that evaluate hosts within their leaf domains.
- Higher-level domain administrators can create white lists that evaluate hosts across domains. You can target different subnets in different domains in the same white list.

Consider a scenario where you are a Global domain administrator, and you want to apply the same compliance criteria to web servers across the entire deployment. You can create one white list in the Global domain that defines the compliance criteria. Then, constrain the white list with target networks that specify the IP space (or individual IP addresses) of the web servers in each leaf domain.

Note In addition to targeting IP addresses and ranges in leaf domains, you can also constrain a target network using a higher-level domain. Targeting a subnet in a higher-level domain targets the **same** subnet in **each** of the descendant leaf domains. The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

Compliance White List Host Profiles

In a compliance white list, host profiles specify which operating systems, clients, application protocols, web applications, and protocols are allowed to run on the target hosts. There are three types of host profile you can use in a compliance white list; each type appears differently in the compliance list editor.

Table 246: Compliance White List Host Profile Types

Host Profile Type	Appearance	Description
global	Any Operating System	specifies what is allowed to run on target hosts, regardless of operating system
operating-system specific	is listed in plain text	specifies what is allowed to run on target hosts of a particular operating system

Host Profile Type	Appearance	Description
shared	is listed in italics	specifies operating-system criteria that can be used in multiple white lists

Operating System-Specific Host Profiles

In a compliance white list, *operating-system specific host profiles* indicate not only which operating systems are allowed to run on your network, but also the application protocols, clients, web applications, and protocols that are allowed to run on those operating systems.

For example, you could require that compliant hosts run a particular version of Microsoft Windows. As another example, you could allow SSH to run on Linux hosts on port 22, and further restrict the vendor and version of the SSH client.

Create one host profile for each operating system you want to allow on your network. To disallow an operating system on your network, do not create a host profile for that operating system. For example, to make sure that all the hosts on your network are running Windows, configure the white list to only contain host profiles for that operating system.

Note Unidentified hosts remain in compliance with all white lists until they are identified. You can, however, create a white list host profile for unknown hosts. *Unidentified* hosts are hosts about which the system has not yet gathered enough information to identify their operating systems. *Unknown* hosts are hosts whose operating systems do not match known fingerprints.

Shared Host Profiles

In a compliance white list, *shared host profiles* are tied to specific operating systems, but you can use each shared host profile in more than one white list.

For example, you might have offices worldwide with a separate white list for each location, but you want to use the same profile for all hosts running Apple Mac OS X. You can create a shared profile for that operating system and use it in all your white lists.

The default white list uses a special category of shared host profiles, called *built-in host profiles*. These profiles use built-in application protocols, web applications, protocols, and clients. In the compliance white list editor, the system marks these profiles with the **Built-In Host Profile icon**.

In a multidomain deployment, the system displays shared host profiles created in the current domain, which you can edit. It also displays shared host profiles from ancestor domains, which you cannot edit. To view and edit shared host profiles created in a lower domain, switch to that domain.

Note If you modify a shared host profile (including built-ins), or modify a built-in application protocol, protocol, or client, your change affects every white list that uses it. If you make unintended changes to or delete these built-in elements, you can reset to factory defaults.

White Violation Triggers

The white list compliance of a host can change when the system:

- detects a change in a host's operating system
- detects an identity conflict for a host's operating system or an application protocol on the host
- detects a new TCP server port (for example, a port used by SMTP or web servers) active on a host, or a new UDP server running on a host
- detects a change in a discovered TCP or UDP server running on a host, for example, a version change due to an upgrade
- detects a new client or web application running on a host
- drops a client or web application from its database due to inactivity
- detects that a host is communicating with a new network or transport protocol
- detects a new jailbroken mobile device
- detects that a TCP or UDP port has closed or timed out on a host

In addition, you can trigger a compliance change for a host by using the host input feature or the host profile to:

- add a client, protocol, or server to a host
- delete a client, protocol, or server from a host
- set the operating system definition for a host
- change a host attribute for a host so that the host is no longer a valid target

Note To avoid overwhelming you with events, the system does not generate white list events for non-compliant hosts on its initial evaluation, nor hosts made non-compliant as a result of you modifying an active white list or shared host profile. The violations, however, are still recorded. If you want to generate white list events for all non-compliant targets, purge discovery data. Rediscovering network assets may trigger white list events.

Operating System Compliance

If your white list specifies that only Microsoft Windows hosts are allowed on your network, and the system detects a host running Mac OS X, the system generates a white list event. In addition, the host attribute associated with the white list changes from Compliant to Non-Compliant for that host.

For the host in this example to come back into compliance, one of the following must occur:

- you edit the white list so that the Mac OS X operating system is allowed
- you manually change the operating system definition of the host to Microsoft Windows
- the system detects that the operating system has changed back to Microsoft Windows

Deleting a Non-Compliant Asset from the Network Map

If your white list disallows the use of FTP, and you then delete FTP from the application protocols network map or from an event view, hosts running FTP become compliant. However, if the system detects the application protocol again, the system generates a white list event and the hosts become non-compliant.

Triggering on Complete Information Only

If your white list allows only TCP FTP traffic on port 21, and the system detects indeterminate activity on port 21/TCP, the white list does not trigger. The white list triggers only when the system identifies the traffic as something other than FTP, or you use the host input feature to designate the traffic as non-FTP traffic. The system does not record a violation with only partial information.

Requirements and Prerequisites for Compliance

Model Support

Supported Domains

Any

User Roles

- Admin

Creating a Compliance White List

When you create a compliance white list, the system prompts you to survey your network to create an initial target and to help you characterize compliant hosts.

Step 1 Choose **Policies** > **Correlation**, then click **White List**.

Step 2 Click **NewWhite List**.

Step 3 Optionally, enter the **IP Address** and **Netmask** for an initial target network. In a multidomain deployment, choose the **Domain** where the target network resides.

Tip To survey the entire monitored network, use the default values of 0.0.0.0/0 and ::/0.

Note After you choose a domain for the target network, you cannot change it. Targeting a subnet in a higher-level domain targets the **same** subnet in **each** of the descendant leaf domains. The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

Step 4 Add the target network:

- Add—To add the target network without a survey, click **Add**.
- Add and Survey Network—To add and survey the target network, click **Add and Survey Network**.
- Skip—To create a white list without surveying your network, click **Skip**.

Step 5 Optionally, enter a new **Name** and **Description** for the white list.

Step 6 Optionally, **Allow Jailbroken Mobile Devices** on your network. Disabling this option causes jailbroken devices to generate white list violations.

Step 7 Add at least one **Target Network** to the white list, as described in Setting Target Networks for a Compliance White List, on page 2099.

Step 8 Characterize compliant hosts using **Allowed Host Profiles**:

- Global Host Profile—To edit the white list's global host profile, click **Any Operating System** and proceed as described in Building White List Host Profiles, on page 2100.
- Edit Surveyed Profiles—To edit an existing operating system-specific host profile created by a network survey, click its name and proceed as described in Building White List Host Profiles, on page 2100.
- Create New Profiles—To create a new operating system-specific host profile for this white list, click **Add** ( ) next to **Allowed Host Profiles**, and proceed as described in Building White List Host Profiles, on page 2100.
- Add Shared Host Profile—To add an existing shared host profile to the white list, click **Add Shared Host Profile**, select the shared host profile you want to add, then click **OK**. Shared host profiles appear in italics.

Step 9 Click **SaveWhite List**.

What to do next

- Add the white list to an active correlation policy as described in Configuring Correlation Policies, on page 2109. The system immediately starts evaluating the white list and generating violations.

Related Topics

Compliance White List Target Networks, on page 2094
Creating a Compliance White List Based on Selected Hosts, on page 2526
Firepower System IP Address Conventions, on page 17

Setting Target Networks for a Compliance White List

When you add a target network, you can survey it to characterize compliant hosts. This survey populates the white list with one host profile for each operating system detected in the survey. These host profiles allow all the clients, application protocols, web applications, and protocols that the system has detected on the applicable operating systems.

Step 1 In the compliance white list editor, click **Add Target Network**.

Step 2 Enter the **IP Address** and **Netmask** for the target network.

Step 3 In a multidomain deployment, choose the **Domain** where the target network resides.

Note After you choose a domain for the target network, you cannot change it. Targeting a subnet in a higher-level domain targets the **same** subnet in **each** of the descendant leaf domains. The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

Step 4 Add the target network:

- Add — To add the target network without a survey, click **Add**.
- Add and Survey Network — To add and survey the target network, click **Add and Survey Network**.

Step 5 Optionally, click the new target to configure it further:

- Name — Enter a new **Name**.
- Add Networks — To target additional hosts, click **Add** (), then enter the **IP Address** and **Netmask**. To exclude the network from white list compliance, select **Exclude**.
- Add Host Attributes — To target hosts with a specific host attribute, click **Add** (), then specify the **Attribute** and its **Value**.
- Add VLANs — To target a VLAN, click **Add** (), then type a VLAN number (for 802.1q VLANs).
- Delete — To remove a target restriction, click **Delete** ().

Step 6 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Related Topics

Compliance White List Target Networks, on page 2094
Firepower System IP Address Conventions, on page 17

Building White List Host Profiles

Host profiles specify the white list's compliance criteria, that is, which operating systems, clients, application protocols, web applications, and protocols are allowed to run on the target hosts.

Every white list has a global host profile which is operating-system agnostic. For example, instead of editing multiple Microsoft Windows and Linux host profiles to allow Mozilla Firefox, you can configure the global host profile to allow Firefox regardless of the operating system where it was detected.

You can also configure operating-system specific host profiles, either unique to one white list or shared across white lists.

Note If you modify a shared host profile (including built-ins), or modify a built-in application protocol, protocol, or client, your change affects every white list that uses it. If you make unintended changes to or delete these built-in elements, you can reset to factory defaults.

Before you begin

- Create or edit a host profile within a white list as described in Editing a Compliance White List, on page 2104, or create or edit a shared host profile as described in Managing Shared Host Profiles, on page 2105.

Step 1 In the compliance white list host profile editor, configure a host profile:

- Name — Type a **Name**.
- Operating System — To restrict the host profile to a specific operating system, use the **OS Vendor**, **OS Name**, and **Version** drop-down lists. Because its purpose is to apply to hosts running any operating system, you cannot restrict a global host profile.
- Application Protocol — To allow an application protocol, click **Add** ( ) and proceed as described in Adding an Application Protocol to a Compliance White List, on page 2101.
- Client — To allow a client, click **Add** ( ) and proceed as described in Adding a Client to a Compliance White List, on page 2102.
- Web Application — To allow a web application, click **Add** ( ) and proceed as described in Adding a Web Application to a Compliance White List, on page 2102.
- Protocol — To allow a protocol, click **Add** ( ) and proceed as described in Adding a Protocol to a Compliance White List, on page 2102.
- Delete — To disallow an item you previously allowed, click **Delete** ( ).
- Edit Properties — To edit the properties of an allowed application protocol, client, or protocol, click its name. The changes you make are reflected in every host profile that uses that element.

Tip Select the appropriate **Allow all...** check box to allow all application protocols, clients, or web applications for hosts matching this profile.

Step 2 To immediately implement all changes made since the last time you saved, click **SaveWhite List** (or **Save All Profiles** if you are editing a shared host profile).

Adding an Application Protocol to a Compliance White List

Using white list host profiles, you can allow application protocols either globally or on specific operating systems. Optionally, you can restrict the application protocol by port, vendor, or version. For example, you could allow a particular version of OpenSSH to run on Linux hosts on port 22/TCP.

Step 1 While you are creating or modifying a compliance white list host profile, click **Add** ( ) next to **Allowed Application Protocols** (or next to **Globally Allowed Application Protocols** if you are modifying the global host profile).

Step 2 You have two options:

- If the application protocols you want to allow are listed, select them. The web interface lists application protocols that have been allowed or are currently allowed by the white list.
- To allow an application protocol not in the list, select **<New Application Protocol>** and click **OK** to display the application protocol editor. Select the application protocol **Type** and **Protocol** you want to allow. Optionally, restrict the application protocol by **port**, **Vendor**, and **Version**.

Note You must type the vendor and version exactly as they would appear in a table view of applications. If you do not specify a vendor or version, the white list allows all vendors and versions as long as the type and protocol match.

Step 3 Click **OK**.

Step 4 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Adding a Client to a Compliance White List

Using white list host profiles, you can allow clients either globally or on specific operating systems. Optionally, you can require that the client be a specific version. For example, you could allow only Microsoft Internet Explorer 10 to run on Microsoft Windows hosts.

Step 1 While you are creating or modifying a compliance white list host profile, click **Add** ( ) next to **Allowed Clients** (or next to **Globally Allowed Clients** if you are modifying the global host profile).

Step 2 You have two options:

- If the clients you want to allow are listed, select them. The web interface lists clients that have been allowed or are currently allowed by the white list.
- To allow a client not in the list, select **<New Client>** and click **OK** to display the client editor. Select the **Client** you want to allow from the drop-down list, and, optionally, restrict the client to an allowed **Version**.

  Note You must type the version exactly as it would appear in a table view of clients. If you do not specify a version, all versions are allowed.

Step 3 Click **OK**.

Step 4 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Adding a Web Application to a Compliance White List

Using white list host profiles, you can allow web applications either globally or on specific operating systems.

Step 1 While you are creating or modifying a compliance white list host profile, click **Add** ( ) next to **Allowed Web Applications** (or next to **Globally Allowed Web Applications** if you are modifying the global host profile).

Step 2 Select the web applications you want to allow.

Step 3 Click **OK**

Step 4 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Adding a Protocol to a Compliance White List

Using white list host profiles, you can allow protocols either globally or on specific operating systems. ARP, IP, TCP, and UDP are always allowed to run on any host; you cannot disallow them.

Step 1 While you are creating or modifying a compliance white list host profile, click **Add** ( ) next to **Allowed Protocols** (or next to **Globally Allowed Protocols** if you are modifying the global host profile).

Step 2 You have two options:

- If the protocols you want to allow are listed, select them. The web interface lists protocols that have been allowed or are currently allowed by the white list.
- To allow a protocol not in the list, select **<New Protocol>** and click **OK** to display the protocol editor. From the **Type** drop-down list, select the protocol type (**Network** or **Transport**), then select the **Protocol** from the drop-down list.

  Tip Select **Other (manual entry)** to specify a protocol that is not in the list. For network protocols, type the appropriate number as listed in http://www.iana.org/assignments/ethernet-numbers/. For transport protocols, type the appropriate number as listed in http://www.iana.org/assignments/protocol-numbers/.

Step 3 Click **OK**.

Step 4 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Managing Compliance White Lists

You can use the White List page to manage compliance white lists and shared host profiles. The default white list represents recommended settings and uses a special category of shared host profiles, called *built-in host profiles*.

In a multidomain deployment, the system displays compliance white lists created in the current domain, which you can edit. It also displays selected white lists from ancestor domains, which you cannot edit. To view and edit white lists created in a lower domain, switch to that domain.

Note The system does not display configurations from ancestor domains if the configurations expose information about unrelated domains, including names, managed devices, and so on. The default white list is only available in the Global domain.

Step 1 Choose **Policies** > **Correlation**, then click **White List**.

Step 2 Manage your compliance white lists:

- Create — To create a new white list, click **NewWhite List** and proceed as described in Creating a Compliance White List, on page 2098.
- Delete — To delete a white list that is not in use, click **Delete** ( ), then confirm you want to delete the white list. Deleting a white list also removes its associated host attribute from all hosts on your network. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Edit — To modify an existing white list, click **Edit** () and proceed as described in Editing a Compliance White List, on page 2104. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Shared Host Profiles — To manage your white lists' shared host profiles, click **Edit Shared Profiles** and proceed as described in Managing Shared Host Profiles, on page 2105.

Editing a Compliance White List

When you modify and save a compliance white list that is included in an active correlation policy, the system immediately re-evaluates the compliance of the hosts in the white list's target networks. Although this re-evaluation may bring some hosts into or out of compliance, the system does not generate any white list events.

Step 1 Choose **Policies** > **Correlation**, then click **White List**.

Step 2 Next to the white list you want to modify, click **Edit** ().

If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your compliance white list:

- Name and Description — To change the name or description, click the white list name in the left panel to display basic white list information, then type the new information.
- Allow Jailbroken Devices — To allow jailbroken mobile devices on your network, click the white list name in the left panel to display basic white list information, then enable **Allow Jailbroken Mobile Devices**. Disabling this option causes jailbroken devices to generate white list violations.
- Add Allowed Host Profile — To create an operating system-specific host profile for this white list, click **Add** () next to Allowed Host Profiles and proceed as described in Building White List Host Profiles, on page 2100.
- Add Shared Host Profile — To add an existing shared host profile to the white list, click **Add Shared Host Profile**, select the shared host profile you want to add, then click **OK**. Shared host profiles appear in italics.
- Add Target Network — To add a new target network without surveying its hosts, click **Add** () next to Target Networks and proceed as described in Setting Target Networks for a Compliance White List, on page 2099.
- Delete Host Profile — To delete a shared or operating-system specific host profile from the white list, click **Delete** () next to the host profile, then confirm your choice. Deleting a shared host profile removes it from the white list, but does not delete the profile or remove it from any other white lists that use it. You cannot delete a white list's global host profile.
- Delete Target Network — To remove a target network from the white list, click **Delete** () next to the network, then confirm your choice.
- Edit Global Host Profile — To edit the white list's global host profile, click **Any Operating System** and proceed as described in Building White List Host Profiles, on page 2100.

- Edit Other Host Profile — To edit a shared or operating-system specific host profile, click the host profile's name and proceed as described in Building White List Host Profiles, on page 2100.
- Edit Target Network — To edit a target network, click the network's name and proceed as directed in Setting Target Networks for a Compliance White List, on page 2099.

Step 4 To immediately implement all changes made since the last time you saved, click **SaveWhite List**.

Managing Shared Host Profiles

In a compliance white list, *shared host profiles* are tied to specific operating systems, but you can use each shared host profile in more than one white list. If you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile.

In a multidomain deployment, the system displays shared host profiles created in the current domain, which you can edit. It also displays shared host profiles from ancestor domains, which you cannot edit. To view and edit shared host profiles created in a lower domain, switch to that domain.

Note If you modify a shared host profile (including built-ins), or modify a built-in application protocol, protocol, or client, your change affects every white list that uses it. If you make unintended changes to or delete these built-in elements, you can reset to factory defaults.

Step 1 Choose **Policies** > **Correlation**, then click **White List**.

Step 2 Click **Edit Shared Profiles**.

Step 3 Manage your shared host profiles:

- Create Shared Host Profile — To create a new shared host profile without surveying hosts, click **Add** ( ) next to Shared Host Profiles and proceed as described in Building White List Host Profiles, on page 2100.
- Create Shared Host Profile by Survey — To create multiple new shared host profiles by surveying a network, click **Add Target Network** and proceed as described in Setting Target Networks for a Compliance White List, on page 2099 .
- Delete — To delete a shared host profile, click **Delete** ( ), then confirm your choice.
- Edit — To modify an existing shared host profile (including a built-in shared host profile), click its name and proceed as described in Building White List Host Profiles, on page 2100.
- Reset Built-In Host Profiles — To reset all built-in host profiles to factory defaults, click **Built-in Host Profiles**, then click **Reset to Factory Defaults** and confirm your choice.

Step 4 To immediately implement all changes made since the last time you saved, click **Save All Profiles**.

CHAPTER 104

Correlation Policies

The following topics describe how to configure correlation policies and rules.

Introduction to Correlation Policies and Rules

You can use the *correlation* feature to respond in real time to threats to your network, using *correlation policies*.

A correlation *policy violation* occurs when the activity on your network triggers either a *correlation rule* or *compliance white list* within an active correlation policy.

Correlation Rules

When a correlation rule in an active correlation policy triggers, the system generates a *correlation event*. Correlation rules can trigger when:

- The system generates a specific type of event (connection, intrusion, malware, discovery, user activity, and so on).
- Your network traffic deviates from its normal profile.

You can constrain correlation rules in the following ways:

- Add a *host profile qualification* to constrain the rule using information from the host profile of a host involved in the triggering event.
- Add a *connection tracker* to a correlation rule so that after the rule's initial criteria are met, the system begins tracking certain connections. Then, a correlation event is generated only if the tracked connections meet additional criteria.
- Add a *user qualification* to a correlation rule to track certain users or groups of users. For example, you can constrain a correlation rule so that it triggers only for a particular user's traffic, or traffic from a specific department.

- Add *snooze periods*. When a correlation rule triggers, a snooze period causes that rule not to trigger again for a specified interval. After the snooze period elapses, the rule can trigger again and start a new snooze period.
- Add *inactive periods*. During inactive periods, correlation rules do not trigger.

Although you can configure correlation rules without licensing your deployment, rules that use unlicensed components do not trigger.

Compliance White Lists

A compliance white list specifies which operating systems, applications (web and client), and protocols are allowed on hosts on your network. When a host violates a white list used in an active correlation policy, the system generates a *white list event*.

Correlation Responses

Responses to correlation policy violations include simple alerts and various remediations (such as scanning a host). You can associate each correlation rule or white list with a single response or group of responses.

If network traffic triggers multiple rules or white lists, the system launches all the responses associated with each rule and white list.

Correlation and Multitenancy

In a multidomain deployment, you can create correlation policies at any domain level, using whatever rules, white lists, and responses are available at that level. Higher-level domain administrators can perform correlation within or across domains:

- Constraining a correlation rule by domain matches events reported by that domain's descendants.
- Higher-level domain administrators can create compliance white lists that evaluate hosts across domains. You can target different subnets in different domains in the same white list.

Note The system builds a separate network map for each leaf domain. Using literal configurations (such as IP addresses, VLAN tags, and usernames) to constrain cross-domain correlation rules can have unexpected results.

Configuring Correlation Policies

Use correlation rules, compliance white lists, alert responses, and remediations to build correlation policies.

In a multidomain deployment, you can create correlation policies at any domain level, using whatever constituent configurations are available at that level.

You can assign a priority to each correlation policy, and to each rule and white list used in that policy. Rule and white list priorities override correlation policy priorities. If network traffic violates the correlation policy, the resultant correlation events display the policy priority value, unless the violated rule or white list has its own priority.

Step 1 Choose **Policies** > **Correlation**.

Step 2 Click **Create Policy**.

Step 3 Enter a **Policy Name** and **Policy Desription**.

Step 4 From the **Default Priority** drop-down list, choose a priority for the policy. Choose **None** to use rule priorities only.

Step 5 Click **Add Rules**, check the rules and white lists that you want to use in the policy, then click **Add**.

Step 6 From the **Priority** list for each rule or white list, choose a priority:

- A priority value from 1 to 5
- **None**
- **Default** to use the policy's default priority

Step 7 Add responses to rules and white lists as described in Adding Responses to Rules and White Lists, on page 2109.

Step 8 Click **Save**.

What to do next

- Activate the policy by clicking the slider.

Adding Responses to Rules and White Lists

You can associate each correlation rule or white list with a single response or group of responses. If network traffic triggers multiple rules or white lists, the system launches all the responses associated with each rule and white list. Note that an Nmap remediation does not launch when used as a response to a traffic profile change.

In a multidomain deployment, you can use responses created in the current domain or in ancestor domains.

Step 1 In the correlation policy editor, next to a rule or white list where you want to add responses, click **Responses**.

Step 2 Under Unassigned Responses, choose the responses you want to launch when the rule or white list triggers, and click the up arrow (^).

Step 3 Click **Update**.

Firepower Management Center Alert Responses, on page 2193
Introduction to Remediations, on page 2155

Managing Correlation Policies

Changes made to active correlation policies take effect immediately.

When you activate a correlation policy, the system immediately begins processing events and triggering responses. Note that the system does not generate white list events for non-compliant hosts on its initial, post-activation evaluation.

In a multidomain deployment, the system displays correlation policies created in the current domain, which you can edit. It also displays selected correlation policies from ancestor domains, which you cannot edit. To view and edit correlation policies created in a lower domain, switch to that domain.

Note The system does not display configurations from ancestor domains if the configurations expose information about unrelated domains, including names, managed devices, and so on.

Step 1 Choose **Policies** > **Correlation**.

Step 2 Manage your correlation policies:

- Activate or Deactivate — Click the slider. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Create — Click **Create Policy**; see Configuring Correlation Policies, on page 2109.
- Edit — Click **Edit** ( ); see Configuring Correlation Policies, on page 2109. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Delete — Click **Delete** ( ). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Configuring Correlation Rules

A simple correlation rule requires only that an event of a certain type occurs. You do not need to provide more specific conditions. For example, correlation rules based on traffic profile changes do not require conditions. You can also create complex correlation rules, with multiple conditions and added constraints.

When you create correlation rule trigger criteria, host profile qualifications, user qualifications, or connection trackers, the syntax varies but the mechanics remain consistent.

Note In a multidomain deployment, constraining a correlation rule by an ancestor domain matches events reported by that domain's descendants.

Before you begin

- Confirm that your deployment is collecting the type of information you want to use to trigger correlation events. For example, the information available for any individual connection or connection summary event depends on several factors, including the detection method, the logging method, and event type. The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

Step 1 Choose **Policies** > **Correlation**, then click **Rule Management**.

Step 2 Click **Create Rule**.

Step 3 Enter a **Rule Name** and **Rule Description**.

Step 4 Optionally, choose a **Rule Group** for the rule.

Step 5 Choose a base event type and, optionally, specify additional trigger criteria for the correlation rule. You can choose the following base event types:

- **an intrusion event occurs**—See Syntax for Intrusion Event Trigger Criteria, on page 2112.
- **a malware event occurs**—See Syntax for Malware Event Trigger Criteria, on page 2114.
- **a discovery event occurs**—See Syntax for Discovery Event Trigger Criteria, on page 2116.
- **user activity is detected** —See Syntax for User Activity Event Trigger Criteria, on page 2119.
- **a host input event occurs**—See Syntax for Host Input Event Trigger Criteria, on page 2120.
- **a connection event occurs**—See Syntax for Connection Event Trigger Criteria, on page 2121.
- **a traffic profile changes**—See Syntax for Traffic Profile Changes, on page 2124.

Step 6 Optionally, further constrain the correlation rule by adding any or all of the following:

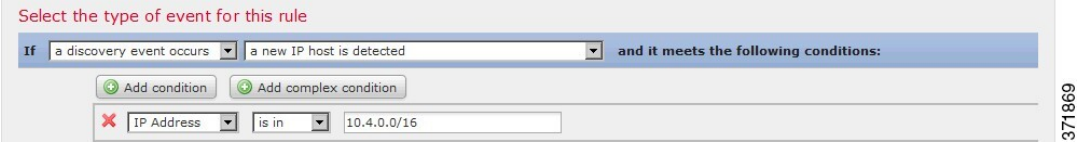
- Host Profile Qualification—Click **Add Host Profile Qualification**; see Syntax for Correlation Host Profile Qualifications, on page 2126.
- Connection Tracker—Click **Add Connection Tracker**; see Connection Trackers, on page 2129.
- User Qualification—Click **Add User Qualification**; see Syntax for User Qualifications, on page 2128.
- Snooze Period—Under Rule Options, use the **Snooze** text field and drop-down list to specify the interval that the system should wait to trigger a correlation rule again, after the rule triggers.
- Inactive Period—Under Rule Options, click **Add Inactive Period**. Using the text field and drop-down lists, specify when and how often you want the system to refrain from evaluating network traffic against the correlation rule.

Tip To remove a snooze period, specify an interval of `0` (seconds, minutes, or hours).

Step 7 Click **Save Rule**.

Example Simple Correlation Rule

The following simple correlation rule triggers if a new host is detected in a specific subnet. Note that when the category represents an IP address, choosing **is in** or **is not in** as the operator allows you to specify whether the IP address *is in* or *is not in* a block of IP addresses, as expressed in special notation such as CIDR.



What to do next

- Use the rule in correlation policies as described in Configuring Correlation Policies, on page 2109.

Syntax for Intrusion Event Trigger Criteria

The following table describes how to build a correlation rule condition when you choose an intrusion event as the base event.

Table 247: Syntax for Intrusion Events

If you specify...	Choose an operator, then...
Access Control Policy	Choose one or more access control policies that use the intrusion policy that generated the intrusion event.
Access Control Rule Name	Enter all or part of the name of the access control rule that uses the intrusion policy that generated the intrusion event.
Application Protocol	Choose one or more application protocols associated with the intrusion event.
Application Protocol Category	Choose one or more category of application protocol.
Classification	Choose one or more classifications.
Client	Choose one or more clients associated with the intrusion event.
Client Category	Choose one or more category of client.
Destination Country or Source Country	Choose one or more countries associated with the source or destination IP address in the intrusion event.

If you specify...	Choose an operator, then...
Destination IP, Source IP, Both Source IP and Destination IP, or Either Source IP or Destination IP	Enter a single IP address or address block.
Destination Port/ICMP Code or Source Port/ICMP Type	Enter the port number or ICMP type for source traffic or the port number or ICMP code for destination traffic.
Device	Choose one or more devices that may have generated the event.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Egress Interface or Ingress Interface	Choose one or more interfaces.
Egress Security Zone or Ingress Security Zone	Choose one or more security zones or tunnel zones.
Generator ID	Choose one or more preprocessors.
Impact Flag	Choose the impact level assigned to the intrusion event. Because no operating system information is available for hosts added to the network map from NetFlow data, the system cannot assign Vulnerable (impact level 1: red) impact levels for intrusion events involving those hosts. In such cases, use the host input feature to manually set the operating system identity for the hosts.
Inline Result	Choose whether the system **dropped** or **would have dropped** packets as a result of the intrusion policy violation. The system can drop packets in an inline, switched, or routed deployment. It does not drop packets in a passive deployment, including when an inline set is in tap mode, regardless of intrusion rule state or the drop behavior of the intrusion policy.
Intrusion Policy	Choose one or more intrusion policies that generated the intrusion event.
IOC Tag	Choose whether an indication of compromise tag was set as a result of the intrusion event.
Priority	Choose the rule priority. For rule-based intrusion events, the priority corresponds to either the value of the `priority` keyword or the value for the `classtype` keyword. For other intrusion events, the priority is determined by the decoder or preprocessor.
Protocol	Enter the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Rule Message	Enter all or part of the rule message.

If you specify...	Choose an operator, then...
Rule SID	Enter a single Snort ID (SID) or multiple SIDs separated by commas. If you choose **is in** or **is not in** as the operator, you cannot use the multi-selection pop-up window. You must enter a comma-separated list of SIDs.
Rule Type	Specify whether the rule is local. Local rules include custom standard text intrusion rules, standard text rules that you modified, and any new instances of shared object rules created when you saved the rule with modified header information.
SSL Actual Action	Choose the SSL rule action that indicates how the system handled an encrypted connection.
SSL Certificate Fingerprint	Enter the fingerprint of the certificate used to encrypt the traffic, or choose a subject common name associated with the fingerprint.
SSL Certificate Subject Common Name (CN)	Enter all or part of the subject common name of the certificate used to encrypt the session.
SSL Certificate Subject Country (C)	Choose one or more subject country codes of the certificate used to encrypt the session.
SSL Certificate Subject Organization (O)	Enter all or part of the subject organization name of the certificate used to encrypt the session.
SSL Certificate Subject Organizational Unit (OU)	Enter all or part of the subject organizational unit name of the certificate used to encrypt the session.
SSL Flow Status	Choose one or more statuses based on the result of the system's attempt to decrypt the traffic.
Username	Enter the username of the user logged into the source host in the intrusion event.
VLAN ID	Enter the innermost VLAN ID associated with the packet that triggered the intrusion event
Web Application	Choose one or more web applications associated with the intrusion event.
Web Application Category	Choose one or more category of web application.

Syntax for Malware Event Trigger Criteria

To base a correlation rule on a malware event, first specify the type of malware event you want to use. Your choice determines the set of trigger criteria you can use. You can choose:

- **by endpoint-based malware detection** (detection by AMP for Endpoints)
- **by network-based malware detection** (detection by AMP for Networks)
- **by retrospective network-based malware detection** (retroactive detection by AMP for Networks)

The following table describes how to build a correlation rule condition when you choose a malware event as the base event.

Table 248: Syntax for Malware Events

If you specify...	Choose an operator, then...
Application Protocol	Choose one or more application protocols associated with the malware event.
Application Protocol Category	Choose one or more category of application protocol.
Client	Choose one or more clients associated with the malware event.
Client Category	Choose one or more category of client.
Destination Country or Source Country	Choose one or more countries associated with the source or destination IP address in the malware event.
Destination IP, Host IP, or Source IP	Enter a single IP address or address block.
Destination Port/ICMP Code	Enter the port number or ICMP code for destination traffic.
Disposition	Choose either or both **Malware** or **Custom Detection**.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Event Type	Choose one or more event types associated with the malware event detected by AMP for Endpoints.
File Name	Enter the name of the file.
File Type	Choose the file type.
File Type Category	Choose one or more file type categories.
IOC Tag	Choose whether an indication of compromise tag **is** or **is not** set as a result of the malware event.
SHA-256	Enter or paste the SHA-256 hash value of the file.
SSL Actual Action	Choose the SSL rule action that indicates how the system handled an encrypted connection.
SSL Certificate Fingerprint	Enter the fingerprint of the certificate used to encrypt the traffic, or choose a subject common name associated with the fingerprint.
SSL Certificate Subject Common Name (CN)	Enter all or part of the subject common name of the certificate used to encrypt the session.
SSL Certificate Subject Country (C)	Choose one or more subject country codes of the certificate used to encrypt the session.

If you specify...	Choose an operator, then...
SSL Certificate Subject Organization (O)	Enter all or part of the subject organization name of the certificate used to encrypt the session.
SSL Certificate Subject Organizational Unit (OU)	Enter all or part of the subject organizational unit name of the certificate used to encrypt the session.
SSL Flow Status	Choose one or more statuses based on the result of the system's attempt to decrypt the traffic.
Source Port/ICMP Type	Enter the port number or ICMP type for source traffic.
Web Application	Choose one or more web applications associated with the malware event.
Web Application Category	Choose one or more category of web application.

Syntax for Discovery Event Trigger Criteria

To base a correlation rule on a discovery event, first specify the type of discovery event you want to use. Your choice determines the set of trigger criteria you can use. The following table lists the discovery event types you can choose.

You cannot trigger a correlation rule on hops changes, or when the system drops a new host due to reaching the host limit. You can, however, choose **there is any type of event** to trigger the rule when any type of discovery event occurs.

Table 249: Correlation Rule Trigger Criteria vs Discovery Event Types

Choose this option...	To use this discovery event type...
a client has changed	Client Update
a client timed out	Client Timeout
a host IP address is reused	DHCP: IP Address Reassigned
a host is deleted because the host limit was reached	Host Deleted: Host Limit Reached
a host is identified as a network device	Host Type Changed to Network Device
a host timed out	Host Timeout
a host's IP address has changed	DHCP: IP Address Changed
a NETBIOS name change is detected	NETBIOS Name Change
a new client is detected	New Client

Choose this option...	To use this discovery event type...
a new IP host is detected	New Host
a new MAC address is detected	Additional MAC Detected for Host
a new MAC host is detected	New Host
a new network protocol is detected	New Network Protocol
a new transport protocol is detected	New Transport Protocol
a TCP port closed	TCP Port Closed
a TCP port timed out	TCP Port Timeout
a UDP port closed	UDP Port Closed
a UDP port timed out	UDP Port Timeout
a VLAN tag was updated	VLAN Tag Information Update
an IOC was set	Indication of Compromise
an open TCP port is detected	New TCP Port
an open UDP port is detected	New UDP Port
the OS information for a host has changed	New OS
the OS or server identity for a host has a conflict	Identity Conflict
the OS or server identity for a host has timed out	Identity Timeout
there is any kind of event	any event type
there is new information about a MAC address	MAC Information Change
there is new information about a TCP server	TCP Server Information Update
there is new information about a UDP server	UDP Server Information Update

The following table describes how to build a correlation rule condition when you choose a discovery event as the base event.

Table 250: Syntax for Discovery Events

If you specify...	Choose an operator, then...
Application Protocol	Choose one or more application protocols.
Application Protocol Category	Choose one or more category of application protocol.
Application Port	Enter the application protocol port number.
Client	Choose one or more clients.

If you specify...	Choose an operator, then...
Client Category	Choose one or more category of client.
Client Version	Enter the version number of the client.
Device	Choose one or more devices that may have generated the discovery event.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Hardware	Enter the hardware model for the mobile device. For example, to match all Apple iPhones, enter `iPhone`.
Host Type	Choose one or more host types. You can choose between a host or one of several types of network device.
IP Address or New IP Address	Enter a single IP address or address block.
Jailbroken	Choose **Yes** to indicate that the host in the event is a jailbroken mobile device or **No** to indicate that it is not.
MAC Address	Enter all or part of the MAC address of the host. For example, if you know that devices from a certain hardware manufacturer have MAC addresses that begin with 0A:12:34, you could choose **begins with** as the operator, then enter `0A:12:34` as the value.
MAC Type	Choose whether the MAC address was **ARP/DHCP Detected**. That is, choose whether the system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**), or whether the system is seeing many hosts with that MAC address because, for example, there is a router between the managed device and the host (**is not ARP/DHCP Detected**).
MAC Vendor	Enter all or part of the name of the MAC hardware vendor of the NIC used by the network traffic that triggered the discovery event.
Mobile	Choose **Yes** to indicate that the host in the event is a mobile device or **No** to indicate that it is not.
NETBIOS Name	Enter the NetBIOS name of the host.
Network Protocol	Enter the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
OS Name	Choose one or more operating system names.
OS Vendor	Choose one or more operating system vendors.

If you specify...	Choose an operator, then...
OS Version	Choose one or more operating system versions.
Protocol or Transport Protocol	Enter the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Source	Choose the source of the host input data (for operating system and server identity changes and timeouts).
Source Type	Choose the type of the source for the host input data (for operating system and server identity changes and timeouts).
VLAN ID	Enter the VLAN ID of the host involved in the event.
Web Application	Choose a web application.

Syntax for User Activity Event Trigger Criteria

To base a correlation rule on user activity, first choose the type of user activity you want to use. Your choice determines the set of trigger criteria you can use. You can choose:

- **a new user identity is detected**
- **a user logs into a host**

The following table describes how to build a correlation rule condition when you choose user activity as the base event.

Table 251: Syntax for User Activity

If you specify...	Choose an operator, then...
Device	Choose one or more devices that may have detected the user activity.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
IP Address	Enter a single IP address or address block.
Username	Enter a username.

Firepower System IP Address Conventions, on page 17

Syntax for Host Input Event Trigger Criteria

To base a correlation rule on a host input event, first specify the type of host input event you want to use. Your choice determines the set of trigger criteria you can use. The following table lists the host input event types you can choose.

You cannot trigger a correlation rule when you add, delete, or change the definition of a user-defined host attribute, or set a vulnerability impact qualification.

Table 252: Correlation Rule Trigger Criteria vs Host Input Event Types

Choose this option...	To trigger the rule on this event type...
a client is added	Add Client
a client is deleted	Delete Client
a host is added	Add Host
a protocol is added	Add Protocol
a protocol is deleted	Delete Protocol
a scan result is added	Add Scan Result
a server definition is set	Set Server Definition
a server is added	Add Port
a server is deleted	Delete Port
a vulnerability is marked invalid	Vulnerability Set Invalid
a vulnerability is marked valid	Vulnerability Set Valid
an address is deleted	Delete Host/Network
an attribute value is deleted	Host Attribute Delete Value
an attribute value is set	Host Attribute Set Value
an OS definition is set	Set Operating System Definition
host criticality is set	Set Host Criticality

The following table describes how to build a correlation rule condition when you choose a host input event as the base event.

Table 253: Syntax for Host Input Events

If you specify...	Choose an operator, then...
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
IP Address	Enter a single IP address or address block.
Source	Choose the source for the host input data.
Source Type	Choose the type of the source for the host input data.

Related Topics

Host Input Event Types, on page 2518

Firepower System IP Address Conventions, on page 17

Syntax for Connection Event Trigger Criteria

To base a correlation rule on a connection event, first specify the type of connection event you want to use. Note that the information available for a connection event can vary depending on how, why, and when the system logged the connection. You can choose:

- **at either the beginning or the end of the connection**
- **at the beginning of the connection**
- **at the end of the connection**

The following table describes how to build a correlation rule condition when you choose a connection event as the base event.

Table 254: Syntax for Connection Events

If you specify...	Choose an operator, then...
Access Control Policy	Choose one or more access control policies that logged the connection.
Access Control Rule Action	Choose one or more actions associated with the access control rule that logged the connection. Choose **Monitor** to trigger correlation events when network traffic matches the conditions of any Monitor rule, regardless of the rule or default action that later handles the connection.
Access Control Rule	Enter all or part of the name of the access control rule that logged the connection. You can enter the name of any Monitor rule whose conditions were matched by a connection, regardless of the rule or default action that later handled the connection.
Application Protocol	Choose one or more application protocols associated with the connection.
Application Protocol Category	Choose one or more categories of application protocol.

If you specify...	Choose an operator, then...
Client	Choose one or more clients.
Client Category	Choose one or more categories of client.
Client Version	Enter the version number of the client.
Connection Duration	Enter the duration of the connection event, in seconds.
Connection Type	Specify whether you want to trigger the correlation rule based on how the connection information was obtained: • Choose **is** and **Netflow** for connection events generated from exported NetFlow data. • Choose **is not** and **Netflow** for connection events detected by a Firepower System managed device.
Destination Country or Source Country	Choose one or more countries associated with the source or destination IP address in the connection event.
Device	Choose one or more devices that either detected the connection, or that processed the connection (for connection data from exported NetFlow records).
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Egress Interface or Ingress Interface	Choose one or more interfaces.
Egress Security Zone or Ingress Security Zone	Choose one or more security zones or tunnel zones.
Initiator Bytes, Responder Bytes, or Total Bytes	Enter one of: • The number of bytes sent (**Initiator Bytes**). • The number of bytes received (**Responder Bytes**). • The number of bytes both sent and received (**Total Bytes**).
Initiator IP, Responder IP, Both Initiator and Responder IP, or Either Initiator IP or Responder IP	Specify a single IP address or address block.
Initiator Packets, Responder Packets, or Total Packets	Enter one of: • The number of packets sent (**Initiator Packets**). • The number of packets received (**Responder Packets**). • The number of packets both sent and received (**Total Packets**)

If you specify...	Choose an operator, then...
Initiator Port/ICMP Type or Responder Port/ICMP Code	Enter the port number or ICMP type for initiator traffic or the port number or ICMP code for responder traffic.
IOC Tag	Specify whether an indication of compromise tag **is** or **is not** set due to the connection event.
NetBIOS Name	Enter the NetBIOS name of the monitored host in the connection.
NetFlow Device	Choose the IP address of the NetFlow exporter you want to use to trigger the correlation rule. If you did not add any NetFlow exporters to the network discovery policy, the **NetFlow Device** drop-down list is blank.
Prefilter Policy	Choose one or more prefilter policies that handled the connection.
Reason	Choose one or more reasons associated with the connection event.
Security Intelligence Category	Choose one or more Security Intelligence categories associated with the connection event. To use Security Intelligence Category as a condition for end-of-connection events, set that category to **Monitor** instead of **Block** in your access control policy.
SSL Actual Action	Specify the SSL rule action that indicates how the system handled an encrypted connection.
SSL Certificate Fingerprint	Enter the fingerprint of the certificate used to encrypt the traffic, or choose a subject common name associated with the fingerprint.
SSL Certificate Status	Choose one or more statuses associated with the certificate used to encrypt the session.
SSL Certificate Subject Common Name (CN)	Enter all or part of the subject common name of the certificate used to encrypt the session.
SSL Certificate Subject Country (C)	Choose one or more subject country codes of the certificate used to encrypt the session.
SSL Certificate Subject Organization (O)	Enter all or part of the subject organization name of the certificate used to encrypt the session.
SSL Certificate Subject Organizational Unit (OU)	Enter all or part of the subject organizational unit name of the certificate used to encrypt the session.
SSL Cipher Suite	Choose one or more cipher suites used to encrypt the session.
SSL Encrypted Session	Choose **Successfully Decrypted**.
SSL Flow Status	Choose one or more statuses based on the result of the system's attempt to decrypt the traffic.
SSL Policy	Choose one or more SSL policies that logged the encrypted connection.
SSL Rule Name	Enter all or part of the name of the SSL rule that logged the encrypted connection.
SSL Server Name	Enter all or part of the name of the server with which the client established an encrypted connection.
SSL URL Category	Choose one or more URL categories for the URL visited in the encrypted connection.
SSL Version	Choose one or more SSL or TLS versions used to encrypt the session.

If you specify...	Choose an operator, then...
TCP Flags	Choose a TCP flag that a connection event must contain in order to trigger the correlation rule. Only connection data generated from NetFlow records contains TCP flags.
Transport Protocol	Enter the transport protocol used by the connection: **TCP** or **UDP**.
Tunnel/Prefilter Rule	Enter all or part of the name of the tunnel or prefilter rule that handled the connection.
URL	Enter all or part of the URL visited in the connection.
URL Category	Choose one or more URL categories for the URL visited in the connection.
URL Reputation	Choose one or more URL reputation values for the URL visited in the connection.
Username	Enter the username of the user logged in to either host in the connection.
Web Application	Choose one or more web applications associated with the connection.
Web Application Category	Choose one or more categories of web application.

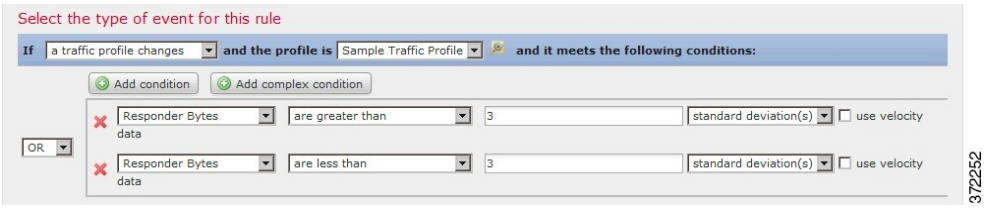
Syntax for Traffic Profile Changes

To base a correlation rule on a traffic profile change, first choose the traffic profile you want to use. The rule triggers when network traffic deviates from the pattern characterized by the profile you choose.

You can trigger the rule based on either raw data or on the statistics calculated from the data. For example, you could write a rule that triggers if the amount of data traversing your network (measured in bytes) suddenly spikes, which could indicate an attack or other security policy violation. You could specify that the rule trigger if either:

- the number of bytes traversing your network spikes above a certain number of bytes
- the number of bytes traversing your network spikes above a certain number of standard deviations above or below the mean amount of traffic

  Note that to create a rule that triggers when the number of bytes traversing your network falls outside a certain number of standard deviations (whether above or below), you must specify upper and lower bounds, as shown in the following graphic.



To create a rule that triggers when the number of bytes traversing is greater than a certain number of standard deviations *above* the mean, use only the first condition shown in the graphic.

To create a rule that triggers when the number of bytes traversing is greater than a certain number of standard deviations *below* the mean, use only the second condition.

Check the **use velocity data** check box to trigger the correlation rule based on rates of change between data points. If you wanted to use velocity data in the above example, you could specify that the rule triggers if either:

- the change in the number of bytes traversing your network spikes above or below a certain number of standard deviations above the mean rate of change
- the change in the number of bytes traversing your network spikes above a certain number of bytes

The following table describes how to build a condition in a correlation rule when you choose a traffic profile change as the base event.

Table 255: Syntax for Traffic Profile Changes

If you specify...	Choose an operator, then enter...	Then choose one of...
Number of Connections	the total number of connections detected **or** the number of standard deviations either above or below the mean that the number of connections detected must be in to trigger the rule	connections standard deviation(s)
Total Bytes, Initiator Bytes, or Responder Bytes	one of: • the total bytes transmitted (**Total Bytes**) • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**) **or** the number of standard deviations either above or below the mean that one of the above criteria must be in to trigger the rule	bytes standard deviation(s)
Total Packets, Initiator Packets, or Responder Packets	one of: • the total packets transmitted (**Total Packets**) • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**) **or** the number of standard deviations either above or below the mean that one of the above criteria must be in trigger the rule	packets standard deviation(s)

If you specify...	Choose an operator, then enter...	Then choose one of...
Unique Initiators	the number of unique hosts that initiated sessions **or** the number of standard deviations either above or below the mean that the number of unique initiators detected must be to trigger the rule	initiators standard deviation(s)
Unique Responders	the number of unique hosts that responded to sessions **or** the number of standard deviations either above or below the mean that the number of unique responders detected must be to trigger the rule	responders standard deviation(s)

Syntax for Correlation Host Profile Qualifications

To constrain a correlation rule based on the host profile of a host involved in the event, add a *host profile qualification*. You cannot add a host profile qualification to a correlation rule that triggers on a malware event, traffic profile change, or on the detection of a new IP host.

When you build a host profile qualification, first specify the host you want to use to constrain your correlation rule. The host you can choose depends on the rule's base event type:

- connection event — Choose **Responder Host** or **Initiator Host**.
- intrusion event — Choose **Destination Host** or **Source Host**.
- discovery event, host input event, or user activity — Choose **Host**.

The following table describes how to build a host profile qualification for a correlation rule.

Table 256: Syntax for Host Profile Qualifications

If you specify...	Choose an operator, then...
Application Protocol > Application Protocol	Choose an application protocol.
Application Protocol > Application Port	Enter the application protocol port number.
Application Protocol > Protocol	Choose a protocol.
Application Protocol Category	Choose a category.
Client > Client	Choose a client.
Client > Client Version	Enter the client version.
Client Category	Choose a category.

If you specify...	Choose an operator, then...
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants.This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Hardware	Enter the hardware model for the mobile device. For example, to match all Apple iPhones, enter `iPhone`.
Host Criticality	Choose the host criticality.
Host Type	Choose one or more host types. You can choose between a normal host or one of several types of network device.
IOC Tag	Choose one or more indication of compromise tags.
Jailbroken	Choose **Yes** to indicate that the host in the event is a jailbroken mobile device or **No** to indicate that it is not.
MAC Address > MAC Address	Enter all or part of the MAC address of the host.
MAC Address > MAC Type	Choose whether the MAC type is ARP/DHCP detected: • the system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**) • the system is seeing many hosts with that MAC address because, for example, there is a router between the device and the host (**is not ARP/DHCP Detected**) • the MAC type is irrelevant (**is any**)
MAC Vendor	Enter all or part of the MAC vendor of hardware used by the host.
Mobile	Choose **Yes** to indicate that the host in the event is a mobile device or **No** to indicate that it is not.
NetBIOS Name	Enter the NetBIOS name of the host.
Network Protocol	Enter the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
Operating System > OS Vendor	Choose one or more operating system vendor names.
Operating System > OS Name	Choose one or more operating system names.
Operating System > OS Version	Choose one or more operating system versions.
Transport Protocol	Enter the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
VLAN ID	Enter the VLAN ID number of the host.
Web Application	Choose a web application.

If you specify...	Choose an operator, then...
Web Application Category	Choose a category.
any available host attribute, including the default compliance white list host attribute	Enter or choose the appropriate value, depending on the host attribute type.

Using Implied or Generic Clients to Build a Host Profile Qualification

When system reports a detected client using an application protocol name followed by `client` (for example, `HTTPS client`) , that client is an *implied* or *generic* client. In these cases, the system has not detected a particular client, but is inferring the existence of a client based on server response traffic.

To create a host profile qualification using an implied or generic client, constrain using the application protocol running on the responder host, not the client.

Using Event Data to Build a Host Profile Qualification

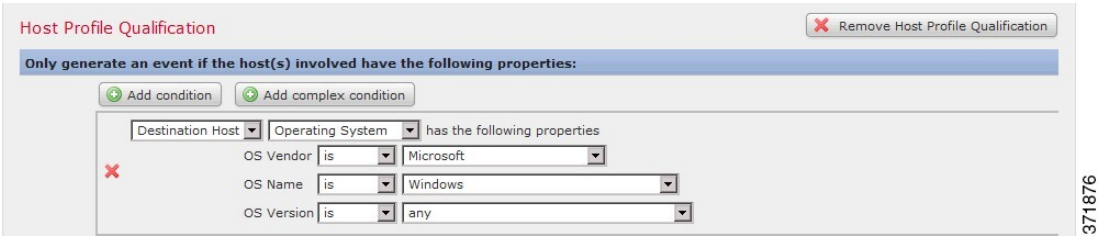
You can often use data from the correlation rule's base event when constructing a host profile qualification.

For example, assume your correlation rule triggers when the system detects the use of a particular browser on one of your monitored hosts. Further assume that when you detect this use, you want to generate an event if the browser version is not the latest.

You could add a host profile qualification to this correlation rule so that the rule triggers only if the **Client** is the **Event Client**, but the **Client Version** is not the latest version.

Example Host Profile Qualification

The following host profile qualification constrains a correlation rule so the rule triggers only if the host involved in the discovery event on which the rule is based is running a version of Microsoft Windows.



Related Topics

Host Data Fields, on page 2522

Syntax for User Qualifications

If you are using a connection, intrusion, discovery, or host input event to trigger your correlation rule, you can constrain the rule based on the identity of a user involved in the event. This constraint is called a *user qualification*. For example, you could constrain a correlation rule so that it triggers only when the identity of the source or destination user is one from the sales department.

You cannot add a user qualification to a correlation rule that triggers on a traffic profile change or on the detection of user activity. Also, the system obtains user details through the Firepower Management Center-server connection established in an identity realm. This information may not be available for all users in the database.

When you build a user qualification, first specify the identity you want to use to constrain your correlation rule. The identity you can choose depends on the rule's base event type:

- connection event — Choose **Identity on Initiator** or **Identity on Responder**.
- intrusion event — Choose **Identity on Destination** or **Identity on Source**.
- discovery event — Choose **Identity on Host**.
- host input event — Choose **Identity on Host**.

The following table describes how to build a user qualification for a correlation rule.

Table 257: Syntax for User Qualifications

If you specify...	Choose an operator, then...
Authentication Protocol	Choose the authentication protocol (or user type) protocol used to detect the user.
Department	Enter a department.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Email	Enter an email address.
First Name	Enter a first name.
Last Name	Enter a last name.
Phone	Enter a telephone number.
Username	Enter a username.

Connection Trackers

A *connection tracker* constrains a correlation rule so that after the rule's initial criteria are met (including host profile and user qualifications), the system begins tracking certain connections. The system generates a correlation event for the rule if the tracked connections meet additional criteria gathered over a time period that you specify.

Tip Connection trackers typically monitor very specific traffic and, when triggered, run only for a finite, specified time. Compare connection trackers with traffic profiles, which typically monitor a broad range of network traffic and run persistently.

There are two ways a connection tracker can generate an event.

Connection Trackers That Fire Immediately When Conditions Are Met

You can configure a connection tracker so that the correlation rule fires as soon as network traffic meets the tracker's conditions. When this happens, the system stops tracking connections for this connection tracker instance, even if the timeout period has not expired. If the same type of policy violation that triggered the correlation rule occurs again, the system creates a new connection tracker.

However, if time expires before network traffic meets the conditions in the connection tracker, the system does not generate a correlation event, and also stops tracking connections for that rule instance.

For example, a connection tracker can serve as a kind of event threshold by generating a correlation event only if a certain type of connection occurs more than a specific number of times within a specific time period. Or, you can generate a correlation event only if the system detects excessive data transfer after an initial connection.

Connection Trackers That Fire at the End of the Timeout Period

You can configure a connection tracker so that it relies on data collected over the entire timeout period, and therefore cannot fire until the end of the timeout period.

For example, if you configure a connection tracker to fire if you detect fewer than a certain number of bytes being transferred during a certain time period, the system waits until that time period passes and then generates an event if network traffic met that condition.

Adding a Connection Tracker

Before you begin

- Create a correlation rule based on a connection, intrusion, discovery, user identity, or host input event. You cannot add a connection tracker to a rule based on a malware event or traffic profile change.

Step 1 In the correlation rule editor, click **Add Connection Tracker**.

Step 2 Specify the connections to track; see Syntax for Connection Trackers, on page 2130.

Step 3 Based on the tracked connections, specify when you want to generate a correlation event; see Syntax for Connection Tracker Events, on page 2133.

Step 4 Specify the interval (in seconds, minutes, or hours) during which the tracker's conditions must be met.

Syntax for Connection Trackers

The following table describes how to build a connection tracker condition that specifies the kind of connections you want to track.

Table 258: Syntax for Connection Trackers

If you specify...	Choose an operator, then...
Access Control Policy	Choose one or more access control policies that handled the connections you want to track.
Access Control Rule Action	Choose one or more access control rule actions associated with the access control rule that logged the connections you want to track. Choose **Monitor** to track connections that match the conditions of any Monitor rule, regardless of the rule or default action that later handles the connections.
Access Control Rule Name	Enter all or part of the name of the access control rule that logged the connections you want to track. To track connections that match a Monitor rule, enter the name of the Monitor rule. The system tracks the connections, regardless of the rule or default action that later handles them.
Application Protocol	Choose one or more application protocols.
Application Protocol Category	Choose one or more application protocol categories.
Client	Choose one or more clients.
Client Category	Choose one or more client categories.
Client Version	Enter the version of the client.
Connection Duration	Enter the connection duration, in seconds.
Connection Type	Specify whether you want to trigger the correlation rule based on how the connection information was obtained: • Choose **is** and **Netflow** for connection events generated from exported NetFlow records. • Choose **is not** and **Netflow** for connection events detected by a Firepower System managed device.
Destination Country or Source Country	Choose one or more countries.
Device	Choose one or more devices whose detected connections you want to track. If you want to track NetFlow connections, choose the devices that process the connection data from exported NetFlow records.
Ingress Interface or Egress Interface	Choose one or more interfaces.
Ingress Security Zone or Egress Security Zone	Choose one or more security zones or tunnel zones.
Initiator IP, Responder IP, or Initiator/Responder IP	Enter a single IP address or address block.

If you specify...	Choose an operator, then...
Initiator Bytes, Responder Bytes, or Total Bytes	Enter one of: • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**) • the number of bytes both transmitted and received (**Total Bytes**)
Initiator Packets, Responder Packets, or Total Packets	Enter one of: • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**) • the number of packets both transmitted and received (**Total Packets**)
Initiator Port/ICMP Type or Responder Port/ICMP Code	Enter the port number or ICMP type for initiator traffic or the port number or ICMP code for responder traffic.
IOC Tag	Choose whether an indication of compromise tag **is** or **is not** set.
NETBIOS Name	Enter the NetBIOS name of the monitored host in the connection.
NetFlow Device	Choose the IP address of the NetFlow exporter you want to track. If you did not add any NetFlow exporters to the network discovery policy, the NetFlow Device drop-down list is blank.
Prefilter Policy	Choose one or more prefilter policies that handled the connections you want to track.
Reason	Choose one or more reasons associated with the connections you want to track.
Security Intelligence Category	Choose one or more Security Intelligence categories associated with the connections you want to track.
TCP Flags	Choose the TCP flag that connections must contain in order to track them. Only connections generated from exported NetFlow records contain TCP flag data.
Transport Protocol	Choose the transport protocol used by the connection.
URL	Enter all or part of the URL visited in the connections you want to track.
URL Category	Choose one or more URL categories for the URL visited in the connections you want to track.
URL Reputation	Choose one or more URL reputation values for the URL visited in the connections you want to track

If you specify...	Choose an operator, then...
Username	Enter the username of the user logged into either host in the connections you want to track.
Web Application	Choose one or more web applications.
Web Application Category	Choose one or more web application categories.

Using Event Data to Build a Connection Tracker

You can often use data from the correlation rule's base event when constructing a connection tracker.

For example, assume your correlation rule triggers when the system detects a new client. When you add a connection tracker to this type of correlation rule, the system automatically populates the tracker with constraints that refer to the base event:

- The **Initiator/Responder IP** is set to the **Event IP Address**.
- The **Client** is set to the **Event Client**.

Tip To track connections for a specific IP address or block of IP addresses, click **switch to manual entry** to manually specify the IP. Click **switch to event fields** to go back to using the IP address in the event.

Syntax for Connection Tracker Events

The following table describes how to how to build a connection tracker condition that specifies when you want to generate a correlation event based on the connections you are tracking.

Table 259: Syntax for Connection Tracker Events

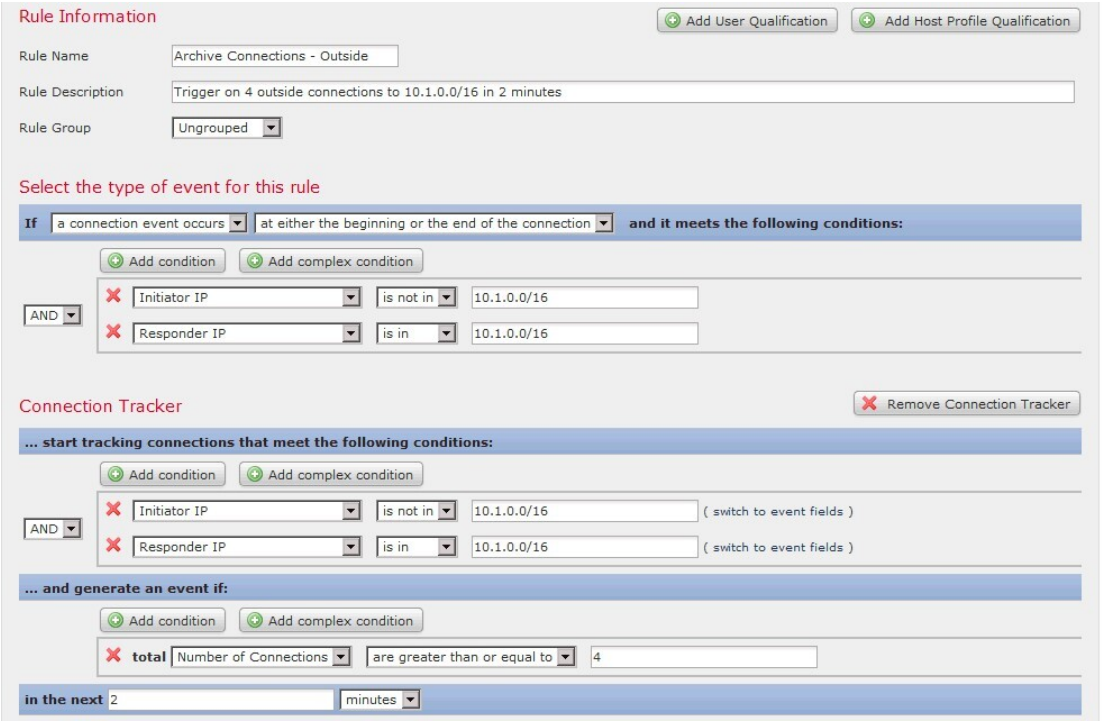
If you specify...	Choose an operator, then enter...
Number of Connections	the total number of connections detected
Number of SSL Encrypted Sessions	the total number of SSL- or TLS-encrypted sessions detected
Total Bytes, Initiator Bytes, or Responder Bytes	one of: • the total bytes transmitted (**Total Bytes**) • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**)

If you specify...	Choose an operator, then enter...
Total Packets, Initiator Packets, or Responder Packets	one of: • the total packets transmitted (**Total Packets**) • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**)
Unique Initiators or Unique Responders	one of: • the number of unique hosts that initiated sessions that were detected (**Unique Initiators**) • the number of unique hosts that responded to connections that were detected (**Unique Responders**)

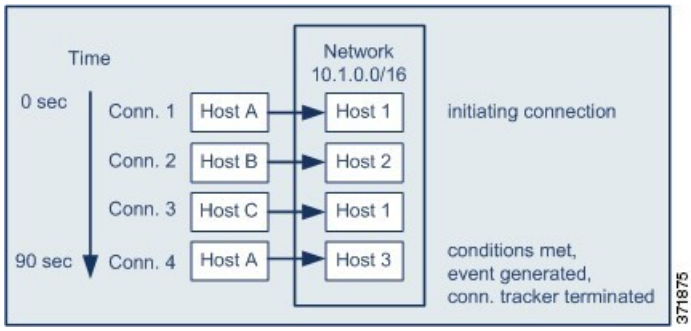
Sample Configuration for Excessive Connections From External Hosts

Consider a scenario where you archive sensitive files on network 10.1.0.0/16, and where hosts outside this network typically do not initiate connections to hosts inside the network. An occasional connection initiated from outside the network might occur, but you have determined that when four or more connections are initiated within two minutes, there is cause for concern.

The rule shown in the following graphic specifies that when a connection occurs from outside the 10.1.0.0/16 network to inside the network, the system begins tracking connections that meet that criterion. The system then generates a correlation event if the system detects four connections (including the original connection) within two minutes that match that signature.



The following diagram shows how network traffic can trigger the above correlation rule.



In this example, the system detected a connection that met the basic conditions of the correlation rule, that is, the system detected a connection from a host outside the 10.1.0.0/16 network to a host inside the network. This created a connection tracker.

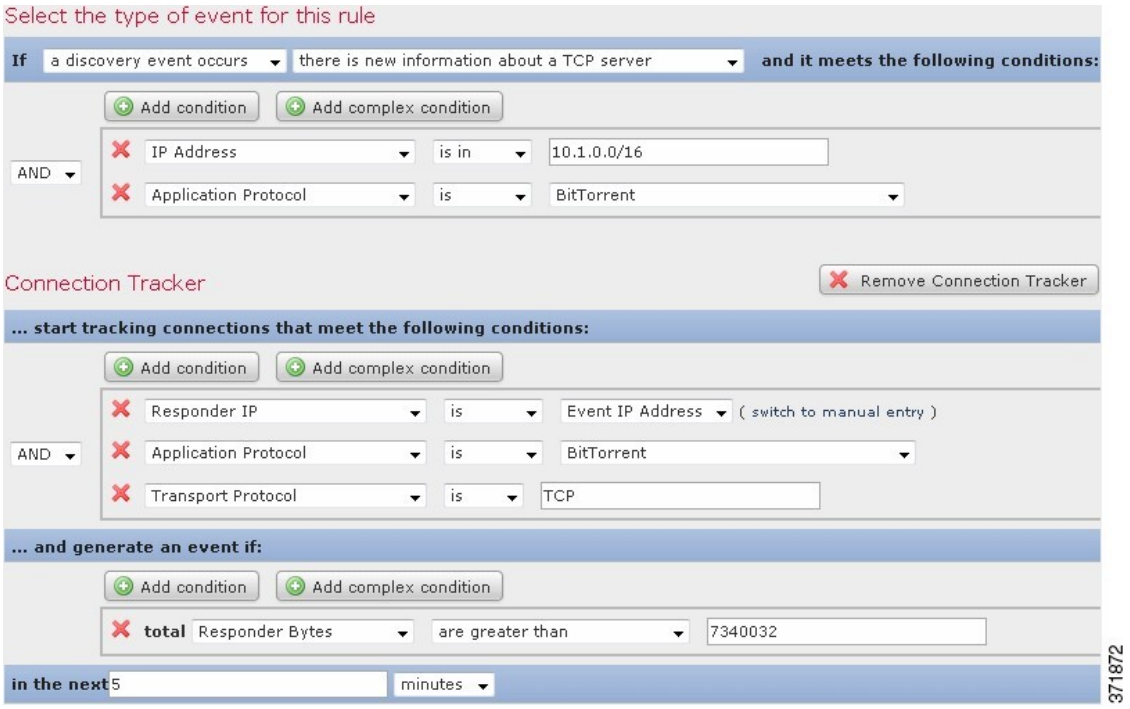
The connection tracker is processed in the following stages:

- First, the system starts tracking connections when it detects a connection from Host A outside the network to Host 1 inside the network.
- The system detects two more connections that match the connection tracker signature: Host B to Host 2 and Host C to Host 1.
- The system detects a fourth qualifying connection when Host A connects to Host 3 within the two-minute time limit. The rule conditions are met.
- Finally, the system generates a correlation event and the system stops tracking connections.

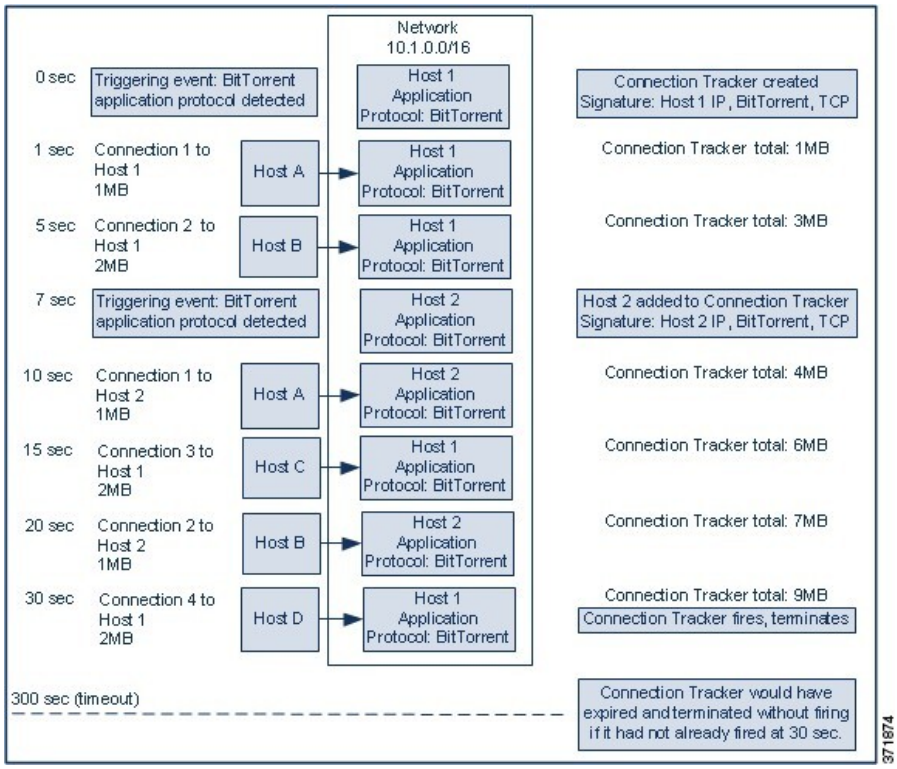
Sample Configuration for Excessive BitTorrent Data Transfers

Consider a scenario where you want to generate a correlation event if the system detects excessive BitTorrent data transfers after an initial connection to any host on your monitored network.

The following graphic shows a correlation rule that triggers when the system detects the BitTorrent application protocol on your monitored network. The rule has a connection tracker that constrains the rule so that the rule triggers only if hosts on your monitored network (in this example, 10.1.0.0/16) collectively transfer more than 7MB of data (7340032 bytes) via BitTorrent in the five minutes following the initial policy violation.



The following diagram shows how network traffic can trigger the above correlation rule.



In this example, the system detected the BitTorrent TCP application protocol on two different hosts: Host 1 and Host 2. These two hosts transmitted data via BitTorrent to four other hosts: Host A, Host B, Host C, and Host D.

This connection tracker is processed in the following stages:

- First, the system starts tracking connections at the 0-second marker when the system detects the BitTorrent application protocol on Host 1. Note that the connection tracker will expire if the system does not detect 7MB of BitTorrent TCP data being transmitted in the next 5 minutes (by the 300-second marker).
- At 5 seconds, Host 1 has transmitted 3MB of data that matches the signature:
  - 1MB from Host 1 to Host A, at the 1-second marker (1MB total BitTorrent traffic counted towards fulfilling the connection tracker)
  - 2MB from Host 1 to Host B, at the 5-second marker (3MB total)
- At 7 seconds, the system detects the BitTorrent application protocol on Host 2 and starts tracking BitTorrent connections for that host as well.
- At 20 seconds, the system has detected additional data matching the signature being transmitted from both Host 1 and Host 2:
  - 1MB from Host 2 to Host A, at the 10-second marker (4MB total)
  - 2MB from Host 1 to Host C, at the 15-second marker (6MB total)
  - 1MB from Host 2 to Host B, at the 20-second marker (7MB total)
- Although Host 1 and Host 2 have now transmitted a combined 7MB of BitTorrent data, the rule does not trigger because the total number of bytes transmitted must be **more** than 7MB (**Responder Bytes are greater than 7340032**). At this point, if the system were to detect no additional BitTorrent transfers for the remaining 280 seconds in the tracker's timeout period, the tracker would expire and the system would not generate a correlation event.
- However, at 30 seconds, the system detects another BitTorrent transfer, and the rule conditions are met:
  - 2MB from Host 1 to Host D at the 30-second marker (9MB total)
- Finally, the system generates a correlation event. The system also stops tracking connections for this connection tracker instance, even though the 5-minute period has not expired. If the system detects a new connection using the BitTorrent TCP application protocol at this point, it will create a new connection tracker. Note that the system generates the correlation event *after* Host 1 transmits the entire 2MB to Host D, because it does not tally connection data until the session terminates.

Snooze and Inactive Periods

You can configure *snooze periods* in correlation rules. When a correlation rule triggers, a snooze period instructs the system to stop firing that rule for a specified interval, even if the rule is violated again during the interval. When the snooze period has elapsed, the rule can trigger again (and start a new snooze period).

For example, you may have a host on your network that should never generate traffic. A simple correlation rule that triggers whenever the system detects a connection involving that host may create multiple correlation events in a short period of time, depending on the network traffic to and from the host. To limit the number of correlation events exposing your policy violation, you can add a snooze period so that the system generates

a correlation event only for the first connection (within a time period that you specify) that the system detects involving that host.

You can also set up inactive periods in correlation rules. During inactive periods, the correlation rule will not trigger. You can set up inactive periods to recur daily, weekly, or monthly. For example, you might perform a nightly Nmap scan on your internal network to look for host operating system changes. In that case, you could set a daily inactive period on the affected correlation rules for the time and duration of your scan so that those rules do not trigger erroneously.

Correlation Rule Building Mechanics

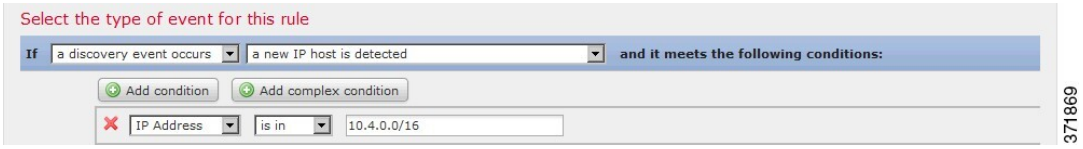
You build a correlation rule by specifying the conditions under which it triggers. The syntax you can use within conditions varies depending on the element you are creating, but the mechanics are the same.

Most conditions have three parts: a *category*, an *operator*, and a *value*:

- The categories you can choose depend on whether you are building correlation rule triggers, a host profile qualification, a connection tracker, or a user qualification. Within correlation rule triggers, the categories further depend on the base event type for the rule. Some conditions may contain several categories, each of which may have their own operators and values.
- A condition's available operators depend on the category.
- The syntax you can use to specify a condition's value depends on the category and operator. Sometimes you type the value in a text field. Other times, you can choose a value (or multiple values) from a drop-down list.

For example, if you want to generate a correlation event every time a new host is detected, you can create a simple rule with no conditions.

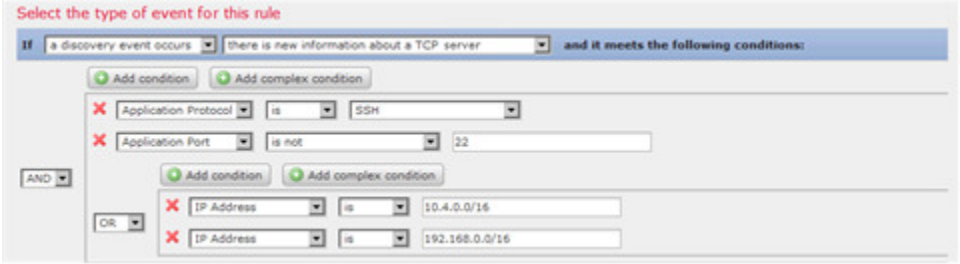
If you want to further constrain the rule and generate an event only if that new host was detected on the 10.4.x.x network, you can add a single condition.



When your construct includes more than one condition, you must link them with an **AND** or an **OR** operator. Conditions on the same level are evaluated together:

- The **AND** operator requires that all conditions on the level it controls must be met.
- The **OR** operator requires that at least one of the conditions on the level it controls must be met.

The following rule, which detects SSH activity on a nonstandard port on the 10.4.x.x network and the 192.168.x.x network, has four conditions, with the bottom two constituting a complex condition.



Logically, the rule is evaluated as follows:

```
(A and B and (C or D))
```

Table 260: Rule Evaluation

Where...	Is the condition that states...
A	Application Protocol is SSH
B	Application Port is not 22
C	IP Address is in 10.0.0.0/8
D	IP Address is in 196.168.0.0/16

Caution Evaluating complex correlation rules that trigger on frequently occurring events can degrade system performance. For example, a multicondition rule that the system must evaluate against every logged connection can cause resource overload.

Adding and Linking Conditions in Correlation Rules

Step 1 In the correlation rule editor, add a simple or complex condition:

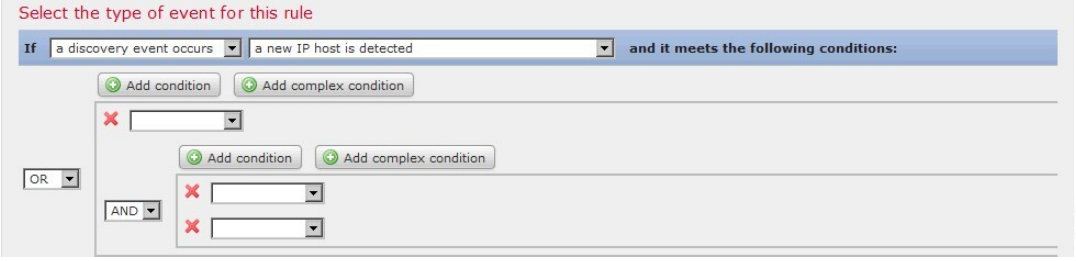
- Simple — Click **Add condition**.
- Complex — Click **Add complex condition**.

Step 2 Link conditions by choosing the **AND** or **OR** operator from the drop-down list to the left of the conditions.

Example: Simple vs Complex Conditions

The following graphic shows a correlation rule with two simple conditions joined by the **OR** operator.

The following graphic shows a correlation rule with one simple condition and one complex condition, joined by the **OR** operator. The complex condition comprises two simple conditions joined by the **AND** operator.



Using Multiple Values in Correlation Rule Conditions

When you are building a correlation condition, and the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list.

Step 1 In the correlation rule editor, build a condition, choosing **is in** or **is not in** as the operator.

Step 2 Click anywhere in the text field or on the **Edit** link.

Step 3 Under **Available**, choose multiple values. You can also click and drag to choose multiple adjacent values.

Step 4 Click the right arrow (>) to move the selected entries to **Selected**.

Step 5 Click **OK**.

Managing Correlation Rules

In a multidomain deployment, the system displays correlation rules and groups created in the current domain, which you can edit. It also displays selected correlation rules and groups from ancestor domains, which you cannot edit. To view and edit correlation rules and groups created in a lower domain, switch to that domain.

Note The system does not display configurations from ancestor domains if the configurations expose information about unrelated domains, including names, managed devices, and so on.

Changes made to rules in active correlation policies take effect immediately.

Before you begin

- If you want to delete a rule, delete it from all correlation policies, as described in Managing Correlation Policies, on page 2110.

Step 1 Choose **Policies** > **Correlation**, then click **Rule Management**.

Step 2 Manage your rules:

- Create — Click **Create Rule**; see Configuring Correlation Rules, on page 2110.

- Create Group — Click **Create Group**, enter a name for the group, and click **Save**. To add a rule to a group, edit the rule.
- Edit — Click **Edit** (); see Configuring Correlation Rules, on page 2110. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Delete Rule or Rule Group— Click **Delete** (). Deleting a rule group ungroups the rules. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Configuring Correlation Response Groups

You can create a *correlation response group* of alerts and remediations, then activate and assign the group to a correlation rule within an active correlation policy. The system launches all the grouped responses when network traffic matches the correlation rule.

When used in an active correlation policy, changes to an active group or any of its grouped responses take affect immediately.

Step 1 Choose **Policies** > **Correlation**, then click **Groups**.

Step 2 Click **Create Group**.

Step 3 Enter a **Name**.

Step 4 Check the **Active** check box if you want to activate the group upon creation.

Deactivated groups do not launch responses.

Step 5 Choose the **Available Responses** to group. then click the right arrow (>) to move them to the **Responses in Group**. To move responses the other way, use the left arrow (<).

Step 6 Click **Save**.

What to do next

- If you did not activate the group upon creation and you want to activate it now, click the slider.

Related Topics

Firepower Management Center Alert Responses, on page 2193
Introduction to Remediations, on page 2155

Managing Correlation Response Groups

You can delete a response group if it is not used in a correlation policy. Deleting a response group ungroups its responses. You can also temporarily deactivate a response group without deleting it. This leaves the group on the system but does not launch it when policies are violated.

In a multidomain deployment, the system displays groups created in the current domain, which you can edit. It also displays groups created in ancestor domains, which you cannot edit. To view and edit groups created in a lower domain, switch to that domain.

Changes made to active, in-use response groups take effect immediately.

Step 1 Choose **Policies** > **Correlation**, then click **Groups**.

Step 2 Manage response groups:

- Activate or Deactivate — Click the slider. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Create — Click **Create Group**; see Configuring Correlation Response Groups, on page 2141.
- Edit — Click **Edit** (); see Configuring Correlation Response Groups, on page 2141. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Delete — Click **Delete** (). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

CHAPTER 105

Traffic Profiling

The following topics describe how to configure traffic profiles:

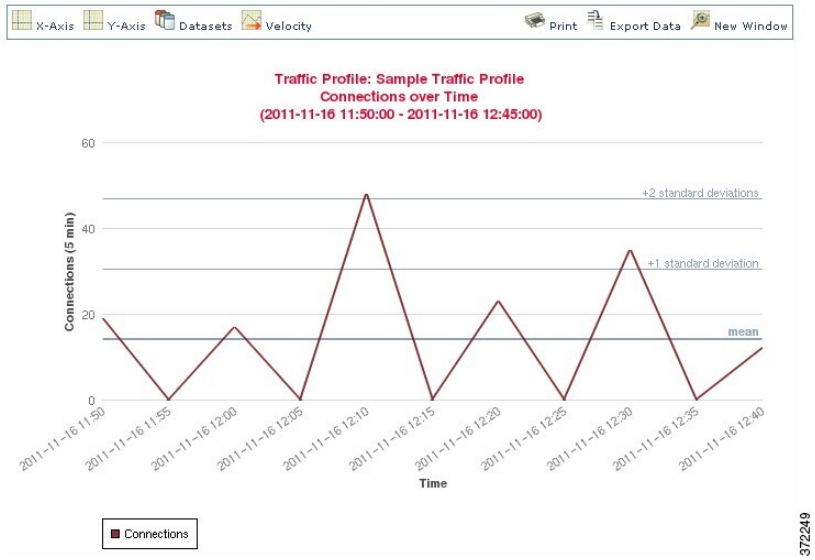
Introduction to Traffic Profiles

A *traffic profile* is a graph of network traffic based on connection data collected over a profiling time window (PTW). This measurement presumably represents normal network traffic. After the learning period, you can detect abnormal network traffic by evaluating new traffic against your profile.

The default PTW is one week, but you can change it to be as short as an hour or as long as several weeks. By default, traffic profiles generate statistics on connection events generated by the system over five-minute intervals. However, you can increase this sampling rate to as long as an hour.

Tip Cisco recommends that the PTW include at least 100 data points. Configure your PTW and sampling rate so that your traffic profiles contain enough data to be statistically meaningful.

The following graphic shows a traffic profile with a PTW of one day and a sampling rate of five minutes.



You can also set up inactive periods in traffic profile. Traffic profiles collect data during inactive periods, but do not use that data when calculating profile statistics. Traffic profile graphs plotted over time show inactive periods as a shaded region.

For example, consider a network infrastructure where all the workstations are backed up at midnight every night. The backup takes about 30 minutes and spikes the network traffic. You could configure recurring inactive period for your traffic profile to coincide with the scheduled backups.

Note The system uses end-of-connection data to create connection graphs and traffic profiles. To use traffic profiles, make sure you log end-of-connection events to the Firepower Management Center database.

Implementing Traffic Profiles

When you activate a traffic profile, the system collects and evaluates connection data for the learning period (PTW) you configured. After the learning period, the system evaluates correlation rules written against the traffic profile.

For example, you could write a rule that triggers if the amount of data traversing your network (measured in packets, KBytes, or number of connections) suddenly spikes to three standard deviations above the mean amount of traffic, which could indicate an attack or other security policy violation. Then, you could include that rule in a correlation policy to alert you of the traffic spike or to perform a remediation in response.

Targeting Traffic Profiles

Profile conditions and *host profile qualifications* constrain traffic profiles.

Using profile conditions, you can profile all network traffic, or you can restrict the traffic profile to monitoring a domain, subnets within or across domains, or individual hosts. In a multidomain deployment:

- Leaf-domain administrators can profile network traffic within their leaf domains.
- Higher-level domain administrators can profile traffic within or across domains.

Profile conditions can also constrain traffic profiles using criteria based on connection data. For example, you could set the profile conditions so that the traffic profile only profiles sessions using a specific port, protocol, or application.

Finally, you can also constrain traffic profiles using information about the tracked hosts. This constraint is called a *host profile qualification*. For example, you could collect connection data only for hosts with high criticality.

Note Constraining a traffic profile to a higher-level domain aggregates and profiles the **same** type of traffic in **each** of the descendant leaf domains. The system builds a separate network map for each leaf domain. In a multidomain deployment, profiling traffic across domains can have unexpected results.

Related Topics

Introduction to Correlation Policies and Rules, on page 2107

Traffic Profile Conditions

You can create simple traffic profile conditions and host profile qualifications, or you can create more elaborate constructs by combining and nesting conditions.

Conditions have three parts: a category, an operator, and a value:

- The categories you can use depend on whether you are building traffic profile conditions or a host profile qualification.
- The operators you can use depend on the category you choose.
- The syntax you can use to specify a condition's value depends on the category and operator. Sometimes you must enter the value in a text field. Other times, you can pick one or more values from a drop-down list.

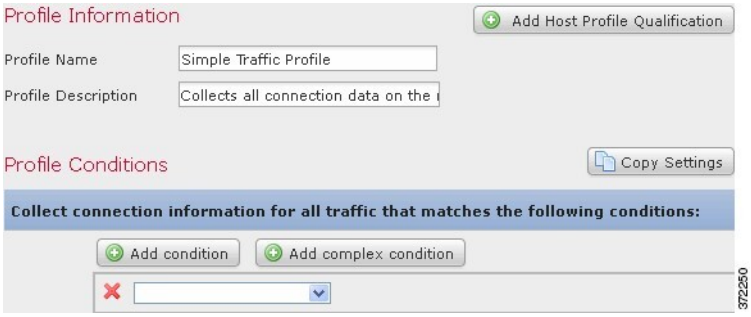
For a host profile qualification, you must also specify whether you are constraining the traffic profile using information data about the initiating or responding hosts.

When your construct includes more than one condition, you must link them with an **AND** or an **OR** operator. Conditions on the same level are evaluated together:

- The **AND** operator requires that all conditions on the level it controls must be met.
- The **OR** operator requires that at least one of the conditions on the level it controls must be met.

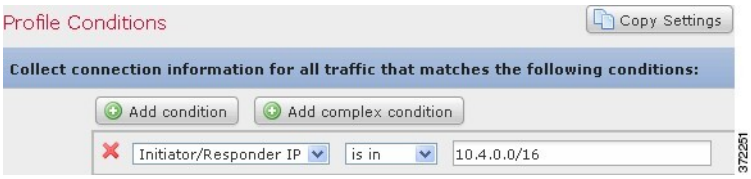
Unconstrained Traffic Profile

If you want to create a traffic profile that collects data for your entire monitored network segment, you can create a very simple profile with no conditions, as shown in the following graphic.



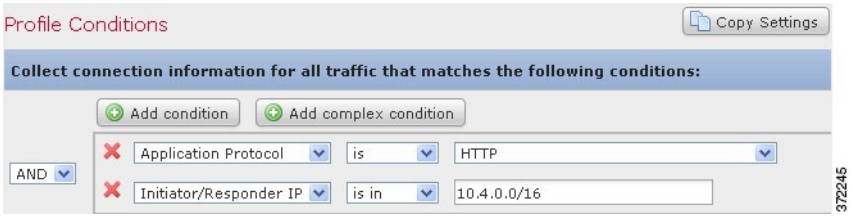
Simple Traffic Profile

If you wanted to constrain the profile and collect data only for a subnet, you can add a single condition, as shown in the following graphic.

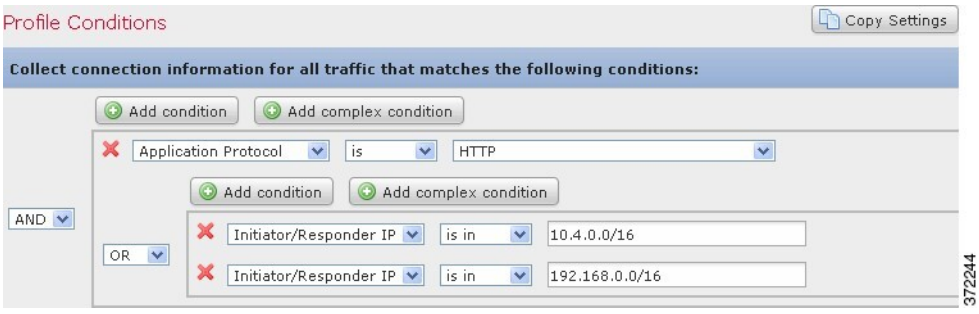


Complex Traffic Profile

The following traffic profile contains two conditions linked by **AND**. This means that the traffic profile collects connection data only if both conditions are true. In this example, it collects HTTP connections for all hosts with IP addresses in a specific subnet.



In contrast, the following traffic profile, which collects connection data for HTTP activity in either of two subnets, has three conditions, with the last constituting a complex condition.



Logically, the above traffic profile is evaluated as follows:

```
(A and (B or C))
```

Where...	Is the condition that states...
A	Application Protocol Name is HTTP
B	IP Address is in 10.4.0.0/16
C	IP Address is in 192.168.0.0/16

Requirements and Prerequisites for Traffic Profiles

Model Support

- Discovery Admin

Managing Traffic Profiles

Only rules written against active, complete traffic profiles can trigger a correlation policy violation. A slider next to each traffic profile indicates whether the profile is active and collecting data. A progress bar shows the status of the traffic profile's learning period.

In a multidomain deployment, the system displays traffic profiles created in the current domain, which you can edit. It also displays selected traffic profiles from ancestor domains, which you cannot edit. To view and edit traffic profiles created in a lower domain, switch to that domain.

Note The system does not display traffic profiles from ancestor domains if the profiles' conditions expose information about unrelated domains, including names, managed devices, and so on.

Step 1 Choose **Policies** > **Correlation**, then click **Traffic Profiles**.

Step 2 Manage your traffic profiles:

- Activate/Deactivate — To activate or deactivate a traffic profile, click the slider. Deactivating a traffic profile deletes its associated data. If you reactivate the profile, you must wait the length of its PTW before rules written against it will trigger.

- Create — To create a new traffic profile, click **New Profile** and proceed as described in Configuring Traffic Profiles, on page 2148. You can also click **Copy** ( ) to edit a copy of an existing traffic profile.
- Delete — To delete a traffic profile, click **Delete** ( ), then confirm your choice.
- Edit — To modify an existing traffic profile, click **Edit** ( ) and proceed as described in Configuring Traffic Profiles, on page 2148. If a traffic profile is active you can only change its name and description.
- Graph — To view the traffic profile as a graph, click **Graph** ( ). In a multidomain deployment, you cannot view the graph for a traffic profile that belongs to an ancestor domain if the graph exposes information about unrelated domains.

Configuring Traffic Profiles

Constraining a traffic profile to a higher-level domain aggregates and profiles the **same** type of traffic in **each** of the descendant leaf domains. The system builds a separate network map for each leaf domain. In a multidomain deployment, profiling traffic across domains can have unexpected results.

Step 1 Choose **Policies** > **Correlation**, then click **Traffic Profiles**.

Step 2 Click **New Profile**.

Step 3 Enter a **Profile Name**, and optionally, a **Profile Description**.

Step 4 Optionally, constrain the traffic profile:

- Copy Settings — To copy settings from an existing traffic profile, click **Copy Settings**, choose the traffic profile you want to use, and click **Load**.
- Profile Conditions — To constrain the traffic profile using information from tracked connections, proceed as described in Adding Traffic Profile Conditions, on page 2149.
- Host Profile Qualification — To constrain the traffic profile using information from tracked hosts, proceed as described in Adding Host Profile Qualifications to a Traffic Profile, on page 2149.
- Profiling Time Window (PTW) — To change the **Profiling Time Window**, enter a time unit, then choose **hour(s)**, **day(s)**, or **week(s)**.
- Sampling Rate — Choose a **Sampling Rate**, in minutes.
- Inactive Period — Click **Add Inactive Period** and use the drop-down lists to specify when and how often you want the traffic profile remain inactive. Inactive traffic profiles do not trigger correlation rules. Traffic profiles do not include data from inactive periods in profile statistics.

Step 5 Save the traffic profile:

- To save the profile and start collecting data immediately, click **Save & Activate**.
- To save the profile without activating it, click **Save**.

Adding Traffic Profile Conditions

Step 1 In the traffic profile editor, under Profile Conditions, click **Add condition** or **Add complex condition** for each condition you want to add. Conditions on the same level are evaluated together.

- To require that all conditions on the level that the operator controls are met, choose **AND**.
- To require that only one of the conditions on the level that the operator controls is met, choose **OR**.

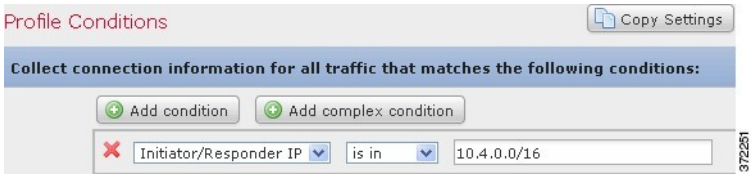
Step 2 Specify a category, operator, and value for each condition as described in Syntax for Traffic Profile Conditions, on page 2150 and Traffic Profile Conditions, on page 2145.

If you choose **is in** or **is not in** as the operator, you can select multiple values in a single condition as described in Using Multiple Values in a Traffic Profile Condition, on page 2153.

When the category represents an IP address, choosing **is in** or **is not in** as the operator allows you to specify whether the IP address *is in* or *is not in* a range of IP addresses.

Example

The following traffic profile collects information on a specific subnet. The category of the condition is **Initiator/Responder IP**, the operator is **is in**, and the value is `10.4.0.0/16`.



Related Topics

Firepower System IP Address Conventions, on page 17

Adding Host Profile Qualifications to a Traffic Profile

Step 1 In the traffic profile editor, click **Add Host Profile Qualification**.

Step 2 Under Host Profile Qualification, click **Add condition** or **Add complex condition** for each condition you want to add. Conditions on the same level are evaluated together.

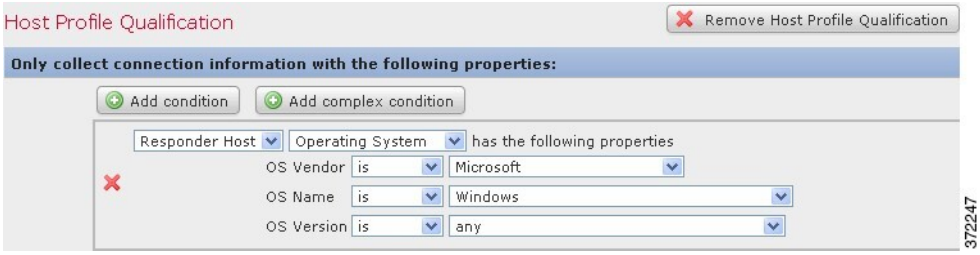
- To require that all conditions on the level that the operator controls are met, choose **AND**.
- To require that only one of the conditions on the level that the operator controls is met, choose **OR**.

Step 3 Specify a host type, category, operator, and value for each condition as described in Syntax for Host Profile Qualifications in a Traffic Profile, on page 2151and Traffic Profile Conditions, on page 2145.

If you choose **is in** or **is not in** as the operator, you can select multiple values in a single condition as described in Using Multiple Values in a Traffic Profile Condition, on page 2153.

Example

The following host profile qualification constrains a traffic profile such that it collects connection data only if the responding host in the detected connection is running a version of Microsoft Windows.



Syntax for Traffic Profile Conditions

The following table describes how to build a traffic profile condition. Keep in mind the connection data available to build a traffic profile depends on several factors, including traffic characteristics and detection method.

Table 261: Syntax for Traffic Profile Conditions

If you choose...	Choose an operator, then...
Application Protocol	Choose one or more application protocols.
Application Protocol Category	Choose one or more application protocol categories.
Client	Choose one or more clients.
Client Category	Choose one or more client categories.
Connection Type	Choose whether the profile uses connection data from traffic monitored by Firepower System managed devices or from exported NetFlow records. If you do not specify a connection type, the traffic profile includes both.
Destination Country or Source Country	Choose one or more countries.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants.
Initiator IP, Responder IP, or Initiator/Responder IP	Enter an IP address or range of IP addresses. The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.
NetFlow Device	Choose the NetFlow exporter whose data you want to use to create the traffic profile.

If you choose...	Choose an operator, then...
Responder Port/ICMP Code	Enter the port number or ICMP code.
Security Intelligence Category	Choose one or more a Security Intelligence categories. To use a Security Intelligence category for a traffic profile condition, that category must be set to **Monitor** instead of **Block** in your access control policy.
SSL Encrypted Session	Choose **Successfully Decrypted**.
Transport Protocol	Enter **`TCP`** or **`UDP`** as the transport protocol.
Web Application	Choose one or more web applications.
Web Application Category	Choose one or more web application categories.

Related Topics

Requirements for Populating Connection Event Fields, on page 2387
Firepower System IP Address Conventions, on page 17

Syntax for Host Profile Qualifications in a Traffic Profile

When you build a host profile qualification condition, you must first choose the host you want to use to constrain your traffic profile. You can choose either **Responder Host** or **Initiator Host**. After you choose the host role, continue building your host profile qualification condition.

Although you can add hosts to the network map using NetFlow records, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. In addition, if your traffic profile uses connection data from exported NetFlow records, keep in mind that NetFlow records do not contain information about which host in the connection is the initiator and which is the responder. When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known.

To match against *implied* or generic clients, create a host profile qualification based on the application protocol used by the server responding to the client. When the client list on a host that acts as the initiator or source of a connection includes an application protocol name followed by **client**, that client may actually be an implied client. In other words, the system reports that client based on server response traffic that uses the application protocol for that client, not on detected client traffic.

For example, if the system reports **HTTPS client** as a client on a host, create a host profile qualification for **Responder Host** where **Application Protocol** is set to **HTTPS**, because HTTPS client is reported as a generic client based on the HTTPS server response traffic sent by the responder or destination host.

Table 262: Syntax for Host Profile Qualifications

If you choose...	Choose an operator, then...
Application Protocol > Application Protocol	Choose one or more application protocols.
Application Protocol > Application Port	Enter the application protocol port number.
Application Protocol > Protocol	Choose the protocol.

If you choose...	Choose an operator, then...
Application Protocol Category	Choose one or more application protocol categories.
Client > Client	Choose one or more clients.
Client > Client Version	Enter the client version.
Client Category	Choose one or more client categories.
Domain	Choose one or more domains. In a multidomain deployment, constraining by an ancestor domain matches data reported by that domain's descendants.
Hardware	Enter a mobile device hardware model. For example, to match all Apple iPhones, enter `iPhone`.
Host Criticality	Choose a host criticality.
Host Type	Choose one or more host types. You can choose between a normal host or one of several types of network device.
IOC Tag	Choose one or more IOC tags.
Jailbroken	Choose **Yes** to indicate that the host in the event is a jailbroken mobile device or **No** to indicate that it is not.
MAC Address > MAC Address	Enter all or part of the MAC address of the host.
MAC Address > MAC Type	Choose whether the MAC type is **ARP/DHCP Detected**, that is, whether: • The system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**) • The system is seeing many hosts with that MAC address because, for example, there is a router between the device and the host (**is not ARP/DHCP Detected**) • The MAC type is irrelevant (**is any**)
MAC Vendor	Enter all or part of the MAC vendor of hardware used by the host.
Mobile	Choose **Yes** to indicate that the host in the event is a mobile device or **No** to indicate that it is not.
NETBIOS Name	Enter the NetBIOS name of the host.
Network Protocol	Enter the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
Operating System > OS Vendor	Choose one or more operating system vendor names.
Operating System > OS Name	Choose one or more operating system names.
Operating System > OS Version	Choose one or more operating system versions.

If you choose...	Choose an operator, then...
Transport Protocol	Enter the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
VLAN ID	Enter the VLAN ID number of the host. The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal VLAN tags to constrain this configuration can have unexpected results.
Web Application	Choose one or more web applications.
Web Application Category	Choose one or more web application categories.
any available host attribute, including the default compliance white list host attribute	Specify the appropriate value, which depends on the type of host attribute you choose: • If the host attribute type is Integer, enter an integer value in the range defined for the attribute. • If the host attribute type is Text, enter a text value. • If the host attribute type is List, choose a valid list string. • If the host attribute type is URL, enter a URL value.

Using Multiple Values in a Traffic Profile Condition

When you are building a condition, and the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list.

For example, if you want to add a host profile qualification to a traffic profile that requires that a host be running some flavor of UNIX, instead of constructing multiple conditions linked with the OR operator, use the following procedure.

Step 1 While building a traffic profile or host profile qualification condition, choose **is in** or **is not in** as the operator. The drop-down list changes to a text field.

Step 2 Click anywhere in the text field or on the **Edit** link.

Step 3 Under **Available**, choose multiple values.

Step 4 Click the right arrow to move the selected entries to **Selected**.

Step 5 Click **OK**.

CHAPTER 106

Remediations

The following topics contain information on configuring remediations:

Requirements and Prerequisites for Remediations

Model Support

Any

Supported Domains

Any

User Roles

- Admin
- Discovery Admin

Introduction to Remediations

A *remediation* is a program that the Firepower System launches in response to a correlation policy violation.

When a remediation runs, the system generates a *remediation status event*. Remediation status events include details such as the remediation name, the correlation policy and rule that triggered it, and the exit status message.

The system supports several remediation modules:

- Cisco ISE Endpoint Protection Services (EPS) — quarantines, unquarantines, or shuts down traffic sent to a host or network involved in a correlation policy violation

- Cisco IOS Null Route — blocks traffic sent to a host or network involved in a correlation policy violation (requires Cisco IOS Version 12.0 or higher)
- Nmap Scanning — scans hosts to determine running operating systems and servers
- Set Attribute Value — sets a host attribute on a host involved in a correlation policy violation

Tip You can install custom modules that perform other tasks; see the *Firepower System Remediation API Guide*.

Implementing Remediations

To implement a remediation, first create at least one *instance* for the module you choose. You can create multiple instances per module, where each instance is configured differently. For example, to communicate with multiple routers using the Cisco IOS Null Route remediation module, configure multiples instances of that module.

You can then add multiple *remediations* to each instance that describe the actions you want to perform when a policy is violated.

Finally, associate remediations with rules in correlation policies, so that the system launches the remediations in response to correlation policy violations.

Remediations and Multitenancy

In a multidomain deployment, you can install custom remediation modules at any domain level. The system-provided modules belong to the Global domain.

Though you cannot add a remediation to an instance created in an ancestor domain, you can create a similarly configured instance in the current domain and add remediations to that instance. You can also use remediations created in ancestor domains as correlation responses.

Related Topics

Firepower Management Center Alert Responses, on page 2193
Nmap Scanning, on page 1953
Adding Responses to Rules and White Lists, on page 2109

Cisco ISE EPS Remediations

If you have Endpoint Protection Service (EPS) enabled and configured in your ISE deployment, you can configure your Firepower Management Center to launch remediations using ISE. When fully configured, ISE EPS remediations run the following **Mitigation Actions** on the source or destination host involved in a correlation policy violation:

- **`quarantine`**—Limits or denies an endpoint's access the network
- **`unquarantine`**—Reverses an endpoint's quarantine status and allows full access to the network
- **`shutdown`**—Deactivates an endpoint's network attached system (NAS) port to disconnect it from the network

You can also exempt specific IP addresses from ISE EPS remediation.

Note Your ISE version and configuration impact how you can use ISE in the Firepower System. For example, you cannot use ISE-PIC to perform ISE EPS remediations. For more information, see The ISE/ISE-PIC Identity Source, on page 2015 for more information.

For more information about ISE EPS actions, see the *Cisco Identity Services Engine User Guide*.

Configuring ISE EPS Remediations

You can respond to correlation policy violations by running ISE EPS remediations on the source or destination host.

Note ISE-PIC cannot perform ISE EPS remediations.

Before you begin

- Configure EPS operations on your ISE server.
- Configure a connection to ISE as described in Configure ISE/ISE-PIC for User Control, on page 2026.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Add a pxGrid mitigation instance as described in Adding an ISE EPS Instance, on page 2157.

Step 3 Add one or more ISE EPS remediations as described in Adding ISE EPS Remediations, on page 2158.

What to do next

- Assign remediations as responses to correlation policy violations as described in Adding Responses to Rules and White Lists, on page 2109.

Adding an ISE EPS Instance

Create ISE EPS instances to group individual remediations by logging type.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 From the **Add a New Instance** list, choose **pxGrid Mitigation(v1.0)** as the module type and click **Add**.

Step 3 Enter an **Instance Name** and **Description**.

Step 4 Set **Enable Logging** option to enable or disable system logging.

Step 5 Click **Create**.

What to do next

- Create an ISE EPS remediation as described in Adding Set Attribute Value Remediations, on page 2164.

Related Topics

Firepower System IP Address Conventions, on page 17

Adding ISE EPS Remediations

Create one or more ISE EPS remediations within an instance to run **Mitigation Actions** on the source or destination host involved in a correlation policy violation.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Create an ISE EPS instance as described in Adding an ISE EPS Instance, on page 2157.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose the **Mitigate Destination** or **Mitigate Source** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 Choose a **Mitigation Action**: **`quarantine`**, **`unquarantine`**, or **`shutdown`**.

Step 6 (Optional) To exempt IP addresses or ranges from remediation, enter them into the **Whitelist** box.

Step 7 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Cisco IOS Null Route Remediations

The Cisco IOS Null Route remediation module allows you to block an IP address or range of addresses using Cisco's "null route" command. This drops all traffic sent to a host or network by routing it to the router's NULL interface. This does not block traffic sent from the violating host or network.

Note Do not use a destination-based remediation as a response to a correlation rule that is based on a discovery or host input event. These events are associated with source hosts.

Caution When a Cisco IOS remediation is activated, there is no timeout period. To unblock the IP address or network, you must manually clear the routing change from the router.

Configuring Remediations for Cisco IOS Routers

Note Do not use a destination-based remediation as a response to a correlation rule that is based on a discovery or host input event. These events are associated with source hosts.

Caution When a Cisco IOS remediation is activated, there is no timeout period. To unblock the IP address or network, you must manually clear the routing change from the router.

Before you begin

- Confirm that your Cisco router is running Cisco IOS 12.0 or higher.
- Confirm that you have level 15 administrative access to the router.

Step 1 Enable Telnet on the Cisco router as described in the documentation provided with your Cisco router or IOS software.

Step 2 On the Firepower Management Center, add a Cisco IOS Null Route instance for each Cisco IOS router you plan to use; see Adding a Cisco IOS Instance, on page 2159.

Step 3 Create remediations for each instance, based on the type of response you want to elicit on the router when correlation policies are violated:

- Adding Cisco IOS Block Destination Remediations, on page 2160
- Adding Cisco IOS Block Destination Network Remediations, on page 2161
- Adding Cisco IOS Block Source Remediations, on page 2161
- Adding Cisco IOS Block Source Network Remediations, on page 2162

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Adding a Cisco IOS Instance

If you have multiple routers where you want to send remediations, create a separate instance for each router.

Before you begin

- Configure Telnet access on the Cisco IOS router as described in the documentation provided with the router or IOS software.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 From the **Add a New Instance** list, choose **Cisco IOS Null Route** and click **Add**.

Step 3 Enter an **Instance Name** and **Description**.

Step 4 In the **Router IP** field, enter the IP address of the Cisco IOS router you want to use for the remediation.

Step 5 In the **Username** field, enter the Telnet user name for the router. This user must have level 15 administrative access on the router.

Step 6 In the **Connection Password** fields, enter the Telnet user's user password.

Step 7 In the **Enable Password** fields, enter the Telnet user's enable password. This is the password used to enter privileged mode on the router.

Step 8 In the **White List** field, enter IP addresses or ranges that you want to exempt from the remediation, one per line.

Note The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

Step 9 Click **Create**.

What to do next

- Add specific remediations to be used by correlation policies as described in Adding Cisco IOS Block Destination Remediations, on page 2160, Adding Cisco IOS Block Destination Network Remediations, on page 2161, Adding Cisco IOS Block Source Remediations, on page 2161, and Adding Cisco IOS Block Source Network Remediations, on page 2162.

Related Topics

Firepower System IP Address Conventions, on page 17

Adding Cisco IOS Block Destination Remediations

The Cisco IOS Block Destination remediation blocks traffic sent from the router to the destination host involved in a correlation policy violation. Do not use this remediation as a response to a correlation rule that is based on a discovery or host input event. These events are associated with source hosts.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Add a Cisco IOS instance as described in Adding a Cisco IOS Instance, on page 2159.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose **Block Destination** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Adding Cisco IOS Block Destination Network Remediations

The Cisco IOS Block Destination Network remediation blocks traffic sent from the router to the network of the destination host involved in a correlation policy violation. Do not use this remediation as a response to a correlation rule that is based on a discovery or host input event. These events are associated with source hosts.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Add a Cisco IOS instance as described in Adding a Cisco IOS Instance, on page 2159.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose **Block Destination Network** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 In the **Netmask** field, enter the subnet mask or use CIDR notation to describe the network that you want to block traffic to.

For example, to block traffic to an entire Class C network when a single host triggered a rule (this is not recommended), use `255.255.255.0` or `24` as the netmask.

As another example, to block traffic to 30 addresses that include the triggering IP address, specify `255.255.255.224` or `27` as the netmask. In this case, if the IP address `10.1.1.15` triggers the remediation, all IP addresses between `10.1.1.1` and `10.1.1.30` are blocked. To block only the triggering IP address, leave the field blank, enter `32`, or enter `255.255.255.255`.

Step 6 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Related Topics

Firepower System IP Address Conventions, on page 17

Adding Cisco IOS Block Source Remediations

The Cisco IOS Block Source remediation blocks traffic sent from the router to the source host involved in a correlation policy violation.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Add a Cisco IOS instance as described in Adding a Cisco IOS Instance, on page 2159.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose **Block Source** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Adding Cisco IOS Block Source Network Remediations

The Cisco IOS Block Source Network remediation blocks traffic sent from the router to the network of the source host involved in a correlation policy violation.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Add a Cisco IOS instance as described in Adding a Cisco IOS Instance, on page 2159.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose **Block Source Network** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 In the **Netmask** field, enter the subnet mask or CIDR notation that describes the network that you want to block traffic to.

For example, to block traffic to an entire Class C network when a single host triggered a rule (this is not recommended), use `255.255.255.0` or `24` as the netmask.

As another example, to block traffic to 30 addresses that include the triggering IP address, specify `255.255.255.224` or `27` as the netmask. In this case, if the IP address `10.1.1.15` triggers the remediation, all IP addresses between `10.1.1.1` and `10.1.1.30` are blocked. To block only the triggering IP address, leave the field blank, enter `32`, or enter `255.255.255.255`.

Step 6 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Related Topics

Firepower System IP Address Conventions, on page 17

Nmap Scan Remediations

The Firepower System integrates with Nmap™, an open source active scanner for network exploration and security auditing. You can respond to a correlation policy violation using an Nmap remediation, which triggers an Nmap scan remediation.

For more information about Nmap scanning, see Nmap Scanning, on page 1953.

Set Attribute Value Remediations

You can respond to a correlation policy violation by setting a host attribute value on the host where the triggering event occurred. For text host attributes, you can use the description from the event as the attribute value.

Configuring Set Attribute Remediations

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Create a set attribute instance as described in Adding a Set Attribute Value Instance, on page 2163.

Step 3 Add a set attribute remediation as described in Adding Set Attribute Value Remediations, on page 2164.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Related Topics

Predefined Host Attributes, on page 2497
User-Defined Host Attributes, on page 2497

Adding a Set Attribute Value Instance

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 From the **Add a New Instance** list, choose **Set Attribute Value** and click **Add**.

Step 3 Enter an **Instance Name** and **Description**.

Step 4 Click **Create**.

What to do next

- Create a set attribute remediation as described in Adding Set Attribute Value Remediations, on page 2164.

Adding Set Attribute Value Remediations

The Set Attribute Value remediation sets a host attribute on a host involved in a correlation policy violation. Create a remediation for each attribute value you want set. For text attributes, you can use the description from the triggering event as the attribute value.

In a multidomain deployment, you cannot add a remediation to an instance created in an ancestor domain.

Before you begin

- Create a set attribute instance as described in Adding a Set Attribute Value Instance, on page 2163.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Next to the instance where you want to add the remediation, click **View** ( ).

Step 3 In the **Configured Remediations** section, choose **Set Attribute Value** and click **Add**.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Remediation Name** and **Description**.

Step 5 To use this remediation in response to an event with source and destination data, choose an **Update Which Host(s) From Event** option.

Step 6 For text attributes, specify whether you want to **Use Description From Event For Attribute Value**:

- To use the description from the event as the attribute value, click **On** and enter the **Attribute Value** you want to set.
- To use the **Attribute Value** setting for the remediation as the attribute value, click **Off**.

Step 7 Click **Create**, then click **Done**.

What to do next

- Assign remediations as responses to correlation policy violations; see Adding Responses to Rules and White Lists, on page 2109.

Managing Remediation Modules

In a multidomain deployment, the system displays remediation modules installed in the current domain, which you can delete. It also displays modules installed in ancestor domains, which you cannot delete. To manage remediation modules in a lower domain, switch to that domain.

Step 1 Choose **Policies** > **Actions** > **Modules**.

Step 2 Manage your remediation modules:

- Configure — To view the Module Detail page for a module and configure its instances and remediations, click **View** (). In a multidomain deployment, you cannot use the Module Detail page to add, delete, or edit instances in the current domain for a module installed in an ancestor domain. Instead, use the Instances page (**Policies** > **Actions** > **Instances**); see Managing Remediation Instances, on page 2165.
- Delete — To delete a custom module that is not in use, click **Delete** (). You cannot delete system-provided modules.
- Install — To install a custom module, click **Choose File**, browse to the module, and click **Install**. For more information, see the *Firepower System Remediation API Guide*.

Managing Remediation Instances

The Instances page lists all configured instances for all remediation modules.

In a multidomain deployment, the system displays remediation instances created in the current domain, which you can edit. It also displays instances created in ancestor domains, which you cannot edit. To manage remediation instances in a lower domain, switch to that domain.

Though you cannot add a remediation to an instance created in an ancestor domain, you can create a similarly configured instance in the current domain and add remediations to that instance. You can also use remediations created in ancestor domains as correlation responses.

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Manage your remediation instances:

- Add—To add an instance, choose the remediation module for which you want to add an instance and click **Add**. For system-provided modules, see:
  - Adding an ISE EPS Instance, on page 2157
  - Adding a Cisco IOS Instance, on page 2159
  - Adding an Nmap Scan Instance, on page 1965
  - Adding a Set Attribute Value Instance, on page 2163

  For help adding a custom module, see the documentation for that module, if available.
- Configure—To configure instance details and add remediations to the instance, click **View** ().

- Delete—To delete an instance that is not in use, click **Delete** ( ).

Managing Instances for a Single Remediation Module

The Module Detail page displays all of the instances and remediations configured for a particular remediation module.

In a multidomain deployment, you can access the Module Detail page for remediation modules installed in the current domain and in ancestor domains. However, you cannot use the Module Detail page to add, delete, or edit instances in the current domain for a module installed in an ancestor domain. Instead, use the Instances page (**Policies** > **Actions** > **Instances**); see Managing Remediation Instances, on page 2165 .

Step 1 Choose **Policies** > **Actions** > **Modules**.

Step 2 Next to the remediation module whose instances you want to manage, click **View** ( ).

Step 3 Manage your remediation instances:

- Add — To add an instance, click **Add**. For system-provided modules, see:
  - Adding an ISE EPS Instance, on page 2157
  - Adding a Cisco IOS Instance, on page 2159
  - Adding an Nmap Scan Instance, on page 1965
  - Adding a Set Attribute Value Instance, on page 2163

  For help adding an instance for a custom module, see the documentation for that module, if available.
- Configure — To configure instance details and add remediations to the instance, click **View** ( ).
- Delete — To delete an instance that is not in use, click **Delete** ( ).

PART XXII

Reporting and Alerting

CHAPTER 107

Working with Reports

The following topics describe how to work with reports in the Firepower System:

Requirements and Prerequisites for Reports

Model Support

Any.

Supported Domains

Any

User Roles

- Admin
- Maintenace User (risk reports only)
- Security Analyst

Introduction to Reports

The Firepower System offers two types of reports:

- Risk Reports, on page 2170 — High-level summaries of risks found on your network.
- Standard Reports, on page 2171 — Detailed, customizable reports about all aspects of your Firepower System.

Risk Reports

Risk reports are portable, high-level, easy-to-interpret summaries of risks found in your organization. You can use these reports to share information about areas of risk, and recommendations for addressing these risks, with people who do not have access to your system and who may not be network security experts. These reports are intended to facilitate discussion about areas for investment in the security of your network.

Generating, Viewing, and Printing Risk Reports

Templates for standard reports do not apply to risk reports.

Reports pertain to the current domain.

Each risk report generates as an HTML file.

To schedule risk report generation, see Automating Report Generation, on page 204.

Before you begin

- Make sure your system is configured to detect the risks that you want to summarize.
- If you want to email the report and you have not yet configured a Relay Host, you can do so now. For information, see Configuring a Mail Relay Host and Notification Address, on page 1045.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Generate Report** for the desired report.

Step 4 Enter information.

- Information that you enter in the Input Parameters section will appear on the title page of the report. You can leave these fields blank.

Step 5 Click **Generate**.

Step 6 Click **OK**.

What to do next

- To view, download, move, or delete a risk report, see About Working with Generated Reports, on page 2189.
- You can print to PDF any risk report from most supported browsers. For best results, enable background colors, images, and optionally headers and footers, in the print or print preview settings of your browser. Supported page sizes are A4 and US letter.

Standard Reports

The Firepower System provides a flexible reporting system that allows you to quickly and easily generate multi-section reports with the event views or dashboards that appear on your Firepower Management Center. You can also design your own custom reports from scratch.

A report is a document file formatted in PDF, HTML, or CSV with the content you want to communicate. A report template specifies the data searches and formats for the report and its sections. The Firepower System includes a powerful report designer that automates the design of report templates. You can replicate the content of any event view table or dashboard graphic displayed in the web interface.

You can build as many report templates as you need. Each report template defines the individual sections in the report and specifies the database search that creates the report's content, as well as the presentation format (table, chart, detail view, and so on) and the time frame. Your template also specifies document attributes, such as the cover page and table of contents and whether the document pages have headers and footers (available only for reports in PDF format). You can export a report template in a single configuration package file and import it for reuse on another Firepower Management Center.

You can include input parameters in a template to expand its usefulness. Input parameters allow you to produce tailored variations of the same report. When you generate a report with input parameters, the generation process prompts you to enter a value for each input parameter. The values you type constrain the report contents on a one-time basis. For example, you can place an input parameter in the destination IP field of the search that produces an intrusion event report; at report generation time, you can specify a department's network segment when prompted for the destination IP address. The generated report then contains only information concerning that particular department.

About Designing Reports

Report Templates

You use report templates to define the content and format of the data in each of the report's sections, as well as the document attributes of the report file (cover page, table of contents, and page headers and footers). After you generate a report, the template stays available for reuse until you delete it.

Your reports contain one or more information sections. You choose the format (text, table, or chart) for each section individually. The format you select for a section may constrain the data that can be included. For example, you cannot show time-based information in certain tables using a pie chart format. You can change the data criteria or format of a section at any time to obtain optimum presentation.

You can base a report's initial design on a predefined event view, or you can start your design by importing content from any defined dashboard, workflow, or summary. You can also start with an empty template, adding sections and defining their attributes one by one.

Note In a multidomain deployment, you can view but not edit report templates belonging to ancestor domains. To generate reports from these templates, you must copy them to your current domain.

Report Template Fields

The following table describes the fields you can use to build a section in your report template. Not all fields are used in all types of sections; after you choose the section format, the system displays the appropriate fields.

Field Name	Section Types	Definition
Format	n/a	Choose the format of the section data: **Bar chart** (): Compares quantities of the selected variables. **Line chart** (): Shows trends/changes over time of a selected variable. Available only for time-based tables. **Pie chart** (): Shows each selected variable as a percentage of the whole. Variables with quantities of zero are dropped from the chart. Very small quantities are clustered into a category labeled **Other**. **Table view** (): Shows values of attributes for each record. Not available for summary or statistical data. **Detail view** (): Shows complex object data associated with certain events, such as packets (for intrusion events) and host profiles (for host events). This format is available only for certain event types that involve such objects. Output may degrade performance if large numbers are requested.
Table	All	Choose the table from which the section data is extracted.
Preset	All	Predefined searches. Select an appropriate preset to initialize the search criteria when you define a new search.
Search or Filter	All	For most tables, you can constrain a report using a predefined or saved **Search**. You can also create a new search by clicking **Edit** (). For the Application Statistics table, you use a user-defined application **Filter** to constrain a report.
X-Axis	Bar chart Line chart Pie chart	Available data for the X-axis of the selected chart. For line charts, the X-axis value is always **Time**. For bar and pie charts, you cannot select **Time** as the X-axis value.
Y-Axis	Bar chart Line chart Pie chart	Available data for the Y-axis of the selected chart.
Section Description	All	Descriptive text that precedes the search data in the section. Enter a combination of text and input parameters. The default for a new section is `$<Time Window>` and `$<Constraints>`.
Time Window	All	The time window for the data that appears in the section. If the section searches time-based tables, you can select the check box to inherit the report's global time window. Alternatively, you can set a specific time window for the section.

Field Name	Section Types	Definition
Maximum Results	Table view Detail view	The maximum number of matching records to include. You can include fewer records in a PDF report than in a CSV or HTML report. The web interface uses warning and error icons to indicate when the number is too large. Hover your pointer over the icon to see the limits.
Results	Bar chart Pie chart	Choose either **Top** or **Bottom** and enter the number of matching records you want to use to build the chart.
Color	Bar chart Line chart	Colors for graphed data in the section.

Report Template Creation

A report template is a framework of sections, each independently built from its own database query.

You can build a new report template by creating a new template, using an existing template, basing a template off an event view, or importing a dashboard or workflow.

If you do not want to copy an existing report template, you can create an entirely new template. The first step in creating a template is to generate the framework that allows you to add and format the sections. Then, in the order you prefer, you design the individual template sections and set attributes for the report document.

Each template section consists of a dataset generated by a search or filter, and has a format specification (table, pie chart, and so on) that determines the mode of presentation. You further determine section content by selecting the fields in the data records you want to include in the output, as well as the time frame and number of records to show.

Note Use the section preview utility to check the column selection and output characteristics such as pie chart colors. It is not a reliable indicator of the correctness of your configured search.

The report you generate from the template has several document attributes that span all sections and control features, such as the cover page, headers and footers, page numbering, and so on.

Note that if you selected CSV as your document format, you have no document attributes to set.

If you identify a good model among your existing templates, you can copy the template and edit its attributes to create a new report template. Cisco also provides a set of predefined report templates, visible on the **Reports Tab** in the list of templates.

From an event view, you can create a report template and modify it to meet your needs. You can add additional sections, modify automatically included sections, and delete sections.

You can quickly create a new report by importing dashboards, workflows, and statistics summaries. The import creates a section for each widget graphic in your dashboard and each event view in your workflow. You can delete any unnecessary sections to focus on the most important information.

Creating a Custom Report Template

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Create Report Template**.

Step 4 Enter a name for your new template in the **Report Title** field.

Step 5 To add an input parameter to the report title, place your cursor in the title where the parameter value should appear, then click insert **Input Parameter** ( ).

Step 6 Use the set of add under the Report Sections title bar to insert sections as necessary.

Step 7 Configure section content as described in Report Template Configuration, on page 2176.

Tip You can click **Preview** at the bottom of the section window to view the column layout or graphic format you chose.

Step 8 Click **Advanced** to set attributes for PDF and HTML reports as described in Document Attributes in a Report Template, on page 2183.

Step 9 Click **Save**.

If you see an error, look for a yellow triangle beside the results value in each section. If you see any such triangles, do one of the following:

- For each field that displays a yellow triangle, mouse over the triangle and reduce the number of results to the number indicated.
- Click **Generate** and include an output format other than PDF.

Creating a Report Template from an Existing Template

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Copy** ( ) next to the report template you want to copy.

Step 4 In the **Report Title** field, enter a name.

Step 5 Make changes to the template as needed.

Step 6 Click **Save**.

Creating a Report Template from an Event View

Step 1 Populate an event view with the events you want in the report:

- Use an event search to define the events you want to view.
- Drill down through a workflow until you have the appropriate events in your event view.

Step 2 From the event view page, click **Report Designer**.

The Report Sections page displays a section for each view in the captured workflow.

Step 3 Optionally, enter a new name in the **Report Title** field and click **Save**.

Step 4 You can:

- Add a cover page, table of contents, starting page number, or header and footer text — Click **Advanced** settings.
- Add page breaks — Click **Add Page Break** (), and drag the new page break object from the template bottom to the front of the section that should start the new page.
- Add text sections — Click **Add Text Section** (), and drag the new text section from the template bottom to the place where you want it to appear in the report template.
- Change the title of a section — Click the section title in the title bar, enter the section title, and click **OK**.
- Configure the report sections — Adjust the field settings in each section.

  Tip To view the current column layout or chart formatting for a section, click the section's **Preview** link.

- Exclude template sections from the report — Click **Delete** ( ) in the section's title bar, and confirm the deletion.

  Note The last report section in some workflows contains detail views that show packets, host profiles, or vulnerabilities, depending on the workflow. Retrieving large numbers of events with these detail views when generating your report may affect performance of the Firepower Management Center.

Step 5 Click **Save**.

Creating a Report Template by Importing a Dashboard or Workflow

Step 1 Identify the dashboard, workflow, or summary you want to replicate in your report.

Step 2 Choose **Overview** > **Reporting**.

Step 3 Click **Report Templates**.

Step 4 Click **Create Report Template**.

Step 5 Enter a name for your new report template in the **Report Title** field.

Step 6 Click **Save**.

Step 7 Click **Import Section** (). You can choose any of the data sources described in Data Source Options on Import Report Sections, on page 2176.

Step 8 Choose a dashboard, workflow, or summary from the drop-down menus.

Step 9 For the data sources you want to add, click **Import**.

For dashboards, each widget graphic will have its own section; for workflows, each event view will have its own section.

Step 10 Make changes to the content of your sections as needed.

Note The last report section in some workflows contains detail views that show packets, host profiles, or vulnerabilities, depending on the workflow. Retrieving large numbers of events with these detail views when generating your report may affect performance of the Firepower Management Center.

Step 11 Click **Save**.

Data Source Options on Import Report Sections

Table 263: Data Source Options on Import Report Sections Window

Select this option...	To import...
Import Dashboard	any custom analysis widget on the selected dashboard.
Import Workflow	any predefined or custom workflow. Selections have the format: `Table - Workflow name` For example, `Connection Events - Traffic by Port` imports the views in the Traffic by Port workflow generated from the Connection Events table.
Import Summary Sections	any of the following generic summaries: • Intrusion Detailed Summary • Intrusion Short Summary • Discovery Detailed Summary • Discovery Short Summary

Report Template Configuration

You can modify and customize a report template once you create it. You can modify a variety of report section attributes to adjust the content of the section and its data presentation.

Each section in a report template queries a database table to generate content for that section. Changing the section's data format uses the same data query, but modifies the fields that appear in the section according to the analytical purpose of the format type. For example, the table view of intrusion events populates the section with a large number of data fields per event record, while a pie chart section shows the portion of all matching records that each selected attribute represents, with no details about individual events. Bar chart sections compare the total counts of matching records that have specific attributes. Line charts summarize changes in the matching records over time with respect to a single attribute. Line charts are available only for data that is time-based, not for information about hosts, users, third-party vulnerabilities, and so on.

The search or filter in a report section specifies the database query on which the section content is based. For most tables, you can constrain a report using a predefined or saved search, or you can create a new search on the fly:

- Predefined searches serve as examples for searching certain event tables and can provide quick access to important information about your network that you may want to include in reports.
- Saved event searches include all public event searches that you or others have created, plus all your saved private event searches.
- Saved searches for the current report template are accessible only in the report template itself. The search names of saved report template searches end with the string "Custom Search." Users create these searches while designing reports.

For the Application Statistics table, you use a user-defined application filter to constrain a report.

If you include table data in a section, you can choose which fields in the data record to show. All fields in the table are available for inclusion or exclusion. You select fields that accomplish the purpose of the report, then order and sort them accordingly.

You can add text sections to your templates to provide custom text, such as an introduction, for the whole report or for individual sections.

You can add page breaks before or after any section in the template. This feature is particularly helpful for multi-section reports with text pages that introduce the various sections.

A report template's time window defines the template's reporting period.

Note Security Analysts can edit only report templates they created. In multidomain deployments, you cannot edit report templates from ancestor domains, but you can copy them to create descendant versions.

Setting the Table and Data Format for a Report Template Section

Step 1 In the report template section, use the **Table** drop-down menu to choose the table to query.

The **Format** field represents each of the output formats available for the table you chose.

Step 2 Choose the applicable output format for the section.

Step 3 To change the search constraints, click **Edit** (✎) next to the **Section description field** or **Filter** field.

Step 4 For graphic output formats (pie chart, bar chart, and so on), adjust the **X-Axis** and **Y-Axis** parameters using the drop-down menus.

When you choose a value for the X-axis, only compatible values appear in the Y-axis drop-down menu, and vice versa.

Step 5 For table output, choose the columns, order of appearance, and sort order in your output.

Step 6 Click **Save**.

Related Topics

Report Template Fields, on page 2172

Specifying the Search or Filter for a Report Template Section

Step 1 In the report template section, choose the database table to query from the **Table** drop-down menu:

- For most tables, the **Search** drop-down list appears.
- For the Application Statistics table, the **Filter** drop-down list appears.

Step 2 Choose the search or filter you want to use to constrain the report.

You can view the search criteria or create a new search by clicking **Edit** (✎).

Related Topics

Application Filters, on page 436

Setting the Search Fields that Appear in Table Format Sections

Step 1 For table format report sections, click **Edit** ( ) next to the **Fields** parameter.

Step 2 If you want to modify the section, you must add and delete fields, and drag field into the column order you want.

Step 3 If you want to change the sort order of any column, you must use the drop-down lists on each field to set the sort order and priority.

Step 4 Click **OK**.

Adding a Text Section to a Report Template

Text sections can have rich text with multiple font sizes and styles (bold, italic, and so on) as well as input parameters and imported images.

Tip Text sections are useful for introductions to your report or your report sections.

Step 1 In the report template editor, click **Add Text Section** ( ).

Step 2 Drag the new text section to its intended position in the report template.

Step 3 If you want to position the text section first or last on a page, add page breaks before or after the text section.

Step 4 If you want to change the text section's generic name, click section's name in the title bar, and enter a new name.

Step 5 Add formatted text and images to the body of the text section.

You can include input parameters that dynamically update when you generate the report.

Step 6 Click **Save**.

Related Topics

Input Parameters, on page 2180

Adding a Page Break to a Report Template

Step 1 In the report template editor, click **Add Page Break** ( ).

A page break appears at the bottom of the template.

Step 2 Drag the page break to its intended location, before or after a section.

Step 3 Click **Save**.

Global Time Windows and Report Template Sections

Report templates with time-based data (such as intrusion or discovery events) have a global time window, which the time-based sections in the template inherit by default when created. Changing the global time window changes the local time window for the sections that are configured to inherit the global time window.

You can disable time window inheritance for an individual section by clearing its **Inherit Time Window** check box. You can then edit the local time window.

Note Global time window inheritance applies only to report sections with data from time-based tables, such as intrusion events and discovery events. For sections that report on network assets (hosts and devices) and related information (such as vulnerabilities), you must set each time window individually.

Setting the Global Time Window for a Report Template and Its Sections

Tip Your report can have different time ranges per section. For example, your first section could be a summary for the month, and the remaining sections could drill down into details at the week level. In such cases, you set the section-level time windows individually.

Step 1 In the report template editor, click **Generate**.

Step 2 To modify the global time window, click **Time Window** ().

Step 3 Modify time settings in **Events Time Window**.

Step 4 Click **Apply**.

Step 5 Click **Generate** to generate the report and **Yes** to confirm.

Setting the Local Time Window for Report Template Sections

Step 1 On the Report Sections page of a template, clear the **Inherit Time Window** check box for the section if it is present.

Step 2 To change the section's local time window, click **Time Window** ().

Note Sections with data from statistics tables can have only sliding time windows.

Step 3 Click **Apply** on the Events Time Window.

Step 4 Click **Save**.

Renaming a Report Template Section

Step 1 In the report template editor, click the current section name in the section header.

Step 2 Enter a new name for the section.

Step 3 Click **OK**.

Previewing a Report Template Section

The preview function shows the field layout and sort order for table views and important legibility characteristics of graphics, such as pie chart colors.

Step 1 At any time while editing a report template section, click **Preview** for the section.

Step 2 Close the preview by clicking **OK**.

Searches in Report Template Sections

The key to generating successful reports is defining the searches that populate the report's sections. The Firepower System provides a search editor to view the searches available in your report templates and to define new custom searches.

Searching in Report Template Sections

Step 1 From the relevant section in the report template, click **Edit** () next to the **Search** field.

Step 2 If you want to base a custom search on a predefined search, you must choose a predefined search from the **Saved Searches** drop-down list.

This list includes all available predefined searches for this table, including system-wide and report-specific predefined searches.

Step 3 Edit the search criteria in the appropriate fields.

For certain fields, your constraints can include the same operators (<, <>, and so on) as event searches. If you enter multiple criteria, the search returns only the records that match all the criteria.

Step 4 If you want to insert an input parameter from the drop-down menu instead of entering a constraint value, you must click **Input Parameter** ().

Note When you edit the constraints of a reporting search, the system saves your edited search under the following name: *section* `custom search`, where *section* is the name in the section title bar followed by the string `custom search`. To have meaningful names for your saved custom searches, be sure you change the section name before you save the edited search. You cannot rename a saved reporting search.

Step 5 Click **OK.**

Input Parameters

You can use input parameters in a report template that the report can dynamically update at generation time. The **Input Parameter** () indicates the fields that can process them. There are two kinds of input parameters:

- *Predefined input parameters* are resolved by internal system functions or configuration information. For example, at report generation time, the system replaces the `$<Time>` parameter with the current date and time.
- *User-defined input parameters* supply constraints in section searches. Constraining a search with an input parameter instructs the system to collect a value at generation time from the person who requests the report. In this way, you can dynamically tailor a report at generation time to show a particular subset of data without changing the template. For example, you can provide an input parameter for the **Destination IP** field of a report section's search. Then, when you generate the report, you can enter the IP network segment for a particular department to get data for that department only.

You can also define string-type input parameters to add dynamic text in certain fields of your report, such as in emails (subject or body), report file names, and text sections. You can personalize reports for different departments, with customized report file names, email addresses, and email messages, using the same template for all.

Predefined Input Parameters

Table 264: Predefined Input Parameters

Insert this parameter...	...to include this information in your template:
`$<Logo>`	The selected uploaded logo
`$<Report Title>`	The report title
`$<Time>`	The date and time of day the report ran, with one-second granularity
`$<Month>`	The current month
`$<Year>`	The current year
`$<System Name>`	The name of the Firepower Management Center
`$<Model Number>`	The model number of the Firepower Management Center
`$<Time Window>`	The time window currently applied to the report section
`$<Constraints>`	The search constraints currently applied to the report section

Table 265: Predefined Input Parameter Usage

Parameter	Report Template Cover Page	Report Template Report Title	Report Template Section Description	Report Template Text Section	Generate Report File Name	Generate Report Email Subject, Body
`$<Logo>`	yes	no	no	no	no	no
`$<Report Title>`	yes	no	yes	yes	yes	yes
`$<Time>`	yes	yes	yes	yes	yes	yes
`$<Month>`	yes	yes	yes	yes	yes	yes
`$<Year>`	yes	yes	yes	yes	yes	yes
`$<System Name>`	yes	yes	yes	yes	yes	yes
`$<Model Number>`	yes	yes	yes	yes	yes	yes
`$<Time Window>`	no	no	yes	no	no	no
`$<Constraints>`	no	no	yes	no	no	no

User-Defined Input Parameters

You use input parameters to expand the usefulness of your searches. The input parameter instructs the system to collect a value at generation time from the person who requests the report. In this way, you can dynamically constrain a report at generation time to show a particular subset of data without changing the search. For example, you can provide an input parameter for the **Destination IP** field of a report section that drills down on security events at a department level. When you generate the report, you can type the IP network segment for a particular department to get data for that department only.

An input parameter's type determines the search fields where you can use it. You can use a given type only in appropriate fields. For example, a user parameter you define as a string type is available for insertion in text fields but not in fields that take an IP address.

Each input parameter you define has a name and a type.

Table 266: User-Defined Input Parameter Types

Use this parameter type...	With fields with this data...
Network/IP	any IP address or network segment in CIDR format
Application	name of an application protocol, client application, or web application
Event Message	any event view message
Device	a FMC or managed device
Username	user identification such as initiator user and responder user
Number (VLAN ID, Snort ID, Vuln ID)	any VLAN ID, Snort ID, or vulnerability ID
String	text fields such as application or OS version, notes, or descriptions

Creating User-Defined Input Parameters

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Add Input Parameter** ( ).

Step 3 Enter the parameter **Name**.

Step 4 Choose a value from the **Type** drop-down list.

Step 5 Click **OK** to add the parameter.

Step 6 Click **OK** to return to the editor.

Editing User-Defined Input Parameters

The **Input Parameters** section of the report template lists all available user-defined parameters for the template.

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Edit** ( ) next to the parameter you want to modify.

Step 3 Enter a new **Name**.

Step 4 Use the **Type** drop-down list to change the parameter type.

Step 5 Click **OK** to save your changes.

Step 6 If you want to delete an input parameter, click **Delete** ( ) next to the input parameter and confirm.

Step 7 Click **OK** to return to the report template editor.

Constraining a Search with User-Defined Input Parameters

Input parameters you define are available only for search fields that match their parameter type. For example, a parameter of type **Network/IP** is available only for fields that accept IP addresses or network segments in CIDR format.

Step 1 In the report template editor, click **Edit** ( ) next to the **Search** field within the section.

Fields that can take an input parameter are marked with **Input Parameter** ( ).

Step 2 Click **Input Parameter** ( ) next to the field, then choose the input parameter from the drop-down menu.

User-defined input parameters are marked with ( ).

Step 3 Click **OK**.

Document Attributes in a Report Template

Before you generate your report, you can set document attributes that affect the report's appearance. These attributes include the optional cover page and table of contents. Support for some attributes depends on the selected report format: PDF, HTML, or CSV.

Table 267: Document Attribute Support

Attribute	PDF Support?	HTML Support?	CSV Support?
Cover page	yes, with optional logo and custom appearance	yes, with optional logo and custom appearance	no
Table of contents	yes	yes	no
Page headers and footers	yes, with optional text or logo in any field	no	no
Custom starting page number	yes	no	no
Option to suppress numbering of first page	yes	no	no

Editing Document Attributes in a Report Template

Step 1 In the report template editor, click **Advanced**.

Step 2 You have the following choices:

- Add cover page —To add a cover page, check the **Include Cover Page** check box.
- Customize cover page —To edit the cover page design, see Customizing a Cover Page, on page 2184.
- Add table of contents — To add a table of contents, check the **Include Table of Contents** check box.
- Manage logos — To manage the logo image associated with the template, see Managing Report Template Logos, on page 2184.
- Configure header and footer —To specify elements for the header and footer of the template, use the drop-down lists in the **Header** and **Footer** fields.
- Set first page number — To specify the page number of the report's first page, enter a **Page Number Start** value.
- Show first page number —To show the page number on the report's first page, check the **Number First Page?** check box. If you choose this option, the cover page is not numbered.

Step 3 Click **OK** to save your changes.

Customizing a Cover Page

You can customize a report template's cover page. Cover pages can have rich text with multiple font sizes and styles (bold, italic, and so on) as well as input parameters and imported images.

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Edit** () next to **Cover Page Design**.

Step 3 Edit the cover page design within the rich text editor.

Step 4 Click **OK**.

Managing Report Template Logos

You can store multiple logos on the Firepower Management Center and associate them with different report templates. You set the logo association when you design the template. If you export the template, the export package contains the logo.

When you upload a logo to the Firepower Management Center, it is available for:

- all report templates on the Firepower Management Center, or
- in a multidomain deployment, all report templates in your current domain

Logo images can be in GIF, JPG, or PNG format.

You can change the logo in a report to any JPG image uploaded to your Firepower Management Center. For example, if you reuse a template, you can associate a logo for a different organization with the report.

You can delete any uploaded logos. Deleting a logo removes it from all templates where it is used. The deletion cannot be undone. Note that you cannot delete the predefined Cisco logo.

Step 1 In the report template editor, click **Advanced**.

The logo currently associated with the template appears under **Logo** in **General Settings**.

Step 2 Click **Edit** (✎) next to the logo.

Step 3 You have the following choices:

- Add — Add a new logo as described in Adding a New Logo, on page 2185.
- Change — Change a report template's logo as described in Changing the Logo for a Report Template, on page 2185.
- Delete — Delete a logo as described in Deleting a Logo, on page 2185.

Adding a New Logo

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Edit** (✎) next to the **Logo** field.

Step 3 Click **Upload Logo**.

Step 4 Click **Browse**, browse to the file's location, and click **Open**.

Step 5 Click **Upload**.

Step 6 If you want to associate the new logo with the current template, choose it, and click **OK**.

Changing the Logo for a Report Template

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Edit** (✎) next to the **Logo** field.

Step 3 From the Select Logo dialog, choose the logo to associate with the report template.

Step 4 Click **OK**.

Deleting a Logo

Step 1 In the report template editor, click **Advanced**.

Step 2 Click **Edit** (✎) next to the **Logo** field.

Step 3 From the Select Logo dialog, choose the logo you want to delete.

Step 4 Click **Delete Logo**.

Step 5 Click **OK**.

Managing Report Templates

In a multidomain deployment, the system displays report templates created in the current domain, which you can edit. It also displays report templates created in ancestor domains, which you cannot edit. To view and

edit report templates in a lower domain, switch to that domain. The system displays reports created in the current domain only.

You must be an Admin user to perform this task.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 You have the following choices:

- Delete — Next to the template you want to delete, click **Delete** ( ) and confirm.

  You cannot delete system-provided report templates. Security Analysts can delete only report templates they created. In a multidomain deployment, you can delete report templates belonging to the current domain only.

- Edit — To edit report templates; see Editing Report Templates, on page 2186.
- Export — To export report templates, see Exporting Report Templates, on page 2187.

  Tip You can also export report templates using the standard configuration export process; see Exporting Configurations, on page 193.

- Import — To import report templates, see Importing Configurations, on page 194.

Editing Report Templates

In a multidomain deployment, the system displays report templates created in the current domain, which you can edit. It also displays report templates created in ancestor domains, which you cannot edit. To view and edit report templates in a lower domain, switch to that domain.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Edit** ( ) for the template you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 You have the following choices:

- Add a page break; see Adding a Page Break to a Report Template, on page 2178.
- Add a text section; see Adding a Text Section to a Report Template, on page 2178.
- Configure section content as described in Report Template Configuration, on page 2176.
- Create input parameters; see Creating User-Defined Input Parameters, on page 2182.
- Edit input parameters; see Editing User-Defined Input Parameters, on page 2182.
- Edit document attributes; see Editing Document Attributes in a Report Template, on page 2184.
- Search template sections; see Searching in Report Template Sections, on page 2180.
- Set document attributes described in Document Attributes in a Report Template, on page 2183 by clicking **Advanced**.
- Set the global time window; see Setting the Global Time Window for a Report Template and Its Sections, on page 2179.
- Set the local time window; see Setting the Local Time Window for Report Template Sections, on page 2179.

- Set the search fields; see Setting the Search Fields that Appear in Table Format Sections, on page 2178.
- Set the table and data format; see Setting the Table and Data Format for a Report Template Section, on page 2177.
- Specify searches and filters; see Specifying the Search or Filter for a Report Template Section, on page 2177.

Exporting Report Templates

You must be an Admin user to perform this task.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Choose **Report Templates**.

Step 3 For the template you want to export, click**YouTube EDU** ( ).

Step 4 Click **Save file** and **OK** to save the file to your local computer.

About Generating Reports

Generating Reports

After you create and customize your report template, you are ready to generate the report. The generation process lets you select the report's format (HTML, PDF, or CSV). You can also adjust the report's global time window, which applies a consistent time frame to all sections except those you exempt.

For PDF reports:

- File names using Unicode (UTF-8) characters are not supported.
- Any report sections that include special Unicode file names (such as those appearing in file or malware events) display these file names in transliterated form.
- The configured number of results configured in each report section must be within certain limits. To view those limits, mouse over any yellow triangles you see in your report template.

If the report template includes user input parameters in its search specification, the generation process prompts you to enter values, which tailor this run of the report to a subset of the data.

If you have a DNS server configured and IP address resolution enabled, reports contain host names if resolution was successful.

In a multidomain deployment, when you generate a report in an ancestor domain, it can include results from all descendant domains. To generate a report for a specific leaf domain, switch to that domain.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Report** ( ) next to the template you want to use to generate a report.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip To generate a report from an ancestor's template, copy the template into the current domain.

Step 4 Optionally, configure the report name:

- Enter a new **File Name**. If you do not enter a new name, the system uses the name specified in the report template.
- Use **Input Parameter** () to add one or more input parameters to the file name.

Step 5 Choose the output format for the report by clicking: HTML, PDF, or CSV.

If the PDF option is dimmed, the configured number of results in one or more report sections may be too high. For specific limits, look for yellow triangles in the report template and hover your mouse over any that you find.

Step 6 If you want to change the global time window, click **Time Window** ().

Note Setting the global time window affects the content of individual report sections only if they are configured to inherit the global setting.

Step 7 Enter values for any fields that appear in the **Input Parameters** section.

Tip You can ignore user parameters by typing the * wildcard character in the field. This eliminates the user parameter's constraint on the search.

Note The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses or VLAN tags to constrain report results can have unexpected results.

Step 8 If you enabled an email relay host in the Firepower Management Center configuration, click **Email** to automate email delivery of the report when it generates.

Step 9 Click **Generate** and confirm when prompted.

Clicking **Generate** saves Generate settings with the report template.

If you click **Close**, your selections are saved only for the duration of your session.

Step 10 You have the following choices:

- Click the report link to display the report in a new window.
- Click **OK** to return to the report template editor.

Report Generation Options

You can configure report generation options to:

- Schedule generation of future reports, either once or recurring. See Automating Report Generation, on page 204. You can customize the schedule on a full range of time frames such as daily, weekly, monthly, and so on.
- Distribute email reports using the scheduler. You must configure your report template and a mail relay host **before** scheduling the task.
- Automatically send the report as an email attachment to a list of recipients when you generate a report. You must have a properly configured mail relay host to deliver a report by email.
- Save newly generated report files to your configured remote storage location. To use remote storage, you must first configure a remote storage location.

Note If you store remotely and then switch back to local storage, the reports in remote storage do not appear on the Reports tab list. Similarly, if you switch from one remote storage location to another, the reports in the previous location do not appear in the list.

Distributing Reports by Email at Generation Time

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Report Templates**.

Step 3 Click **Report** () next to the template you want to use to generate a report.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip To generate a report from an ancestor's template, copy the template into the current domain.

Step 4 Expand the **Email** section of the window.

Step 5 In the **Email Options** field, choose **Send Email**.

Step 6 In the **Recipient List**, **CC**, and **BCC** fields, enter recipients' email addresses in comma-separated lists.

Step 7 In the **Subject** field, enter an email subject.

Tip You can provide input parameters in the **Subject** field and the message body to dynamically generate information in the email, such as a timestamp or the name of the Firepower Management Center.

Step 8 Enter a cover letter in the email body as necessary.

Step 9 Click **OK** and confirm.

Configuring a Mail Relay Host and Notification Address, on page 1045

Schedule Future Reports

See Automating Report Generation, on page 204.

About Working with Generated Reports

Access and work with previously-generated reports on the Reports tab page.

Viewing Reports

The Reports lists all previously generated reports, with report name, date and time of generation, generating user, and whether the report is stored locally or remotely. A status column indicates whether the report is

already generated, is in the generation queue (for example, for scheduled tasks), or failed to generate (for example, due to lack of disk space).

Note that users with Administrator access can view all reports; other users can view only the reports they generated.

In a multidomain deployment, you can view reports generated in the current domain only.

The Reports page shows all locally stored reports. It shows remotely stored reports as well, if remote storage is currently configured. The **Location** column data for remotely-stored reports is `Remote`.

Note If you store remotely and then switch back to local storage, the reports in remote storage do not appear on the Reports tab list. Similarly, if you switch from one remote storage location to another, the reports in the previous location do not appear in the list.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Reports**.

Step 3 Click the report you want to view.

Downloading Reports

You can download any report file to your local computer. From there, you can email it or distribute it electronically by other available means.

In a multidomain deployment, you can download reports generated in the current domain only.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Reports**.

Step 3 Check the check boxes next to the reports you want to download, then click **Download**.

Tip Click the check box at the top left of the page to download all reports on the page. If you have multiple pages of reports, a second check box appears that you can click to download all reports on all pages.

Step 4 Follow your browser's prompts to download the reports. If you chose multiple reports, they are downloaded in a single `.zip` file.

Storing Reports Remotely

The location of your currently configured report storage appears at the bottom of the Overview> Reporting > Reports page, with disk usage for local, NFS, and SMB storage. If you access remote storage using SSH, disk usage data is not available.

Note If you store remotely and then switch back to local storage, the reports in remote storage do not appear on the Reports tab list. Similarly, if you switch from one remote storage location to another, the reports in the previous location do not appear in the list.

Before you begin

- Configure a remote storage location as described in Remote Storage Management, on page 1030.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Choose **Reports**.

Step 3 Check the **Enable Remote Storage of Reports** check box at the bottom of the page.

What to do next

- Move reports from local storage to remote storage; see Moving Reports to Remote Storage, on page 2191.

Related Topics

Remote Storage Management, on page 1030
Moving Reports to Remote Storage, on page 2191

Moving Reports to Remote Storage

You can move your reports in local storage to a remote storage location in batch mode or singly.

Note If you store remotely and then switch back to local storage, the reports in remote storage do not appear on the Reports tab list. Similarly, if you switch from one remote storage location to another, the reports in the previous location do not appear in the list.

Before you begin

- Configure a remote storage location as described in Remote Storage Management, on page 1030.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Choose **Reports**.

Step 3 Choose the check boxes next to the reports you want to move, then click **Move**.

Tip Check the check box at the top left of the page to move all reports on the page. If you have multiple pages of reports, a second check box appears that you can check to move all reports on all pages.

Step 4 Confirm that you want to move the reports.

Deleting Reports

You can delete your report files at any time. The procedure completely removes the files, and no recovery is possible. Although you still have the report template that generated the report, it may be difficult to regenerate a particular report file if the time window was expanding or sliding. Regeneration may also be difficult if your template uses input parameters.

In a multidomain deployment, you can delete reports generated in the current domain only.

Step 1 Choose **Overview** > **Reporting**.

Step 2 Click **Reports**.

Step 3 You have the following choices:

- Delete selected — Check the check boxes next to the reports you want to delete, then click **Delete**.
- Delete all — Check the check box at the top left of the page to delete all reports on the page. If you have multiple pages of reports, a second check box appears that you can check to delete all reports on all pages.

Step 4 Confirm the deletion.

CHAPTER 108

External Alerting with Alert Responses

The following topics describe how to send external event alerts from the Firepower Management Center using alert responses:

Firepower Management Center Alert Responses

External event notification via SNMP, syslog, or email can help with critical-system monitoring. The Firepower Management Center uses configurable *alert responses* to interact with external servers. An *alert response* is a configuration that represents a connection to an email, SNMP, or syslog server. They are called *responses* because you can use them to send alerts in response to events detected by Firepower. You can configure multiple alert responses to send different types of alerts to different monitoring servers and/or people.

Note Depeding on your device and Firepower version, alert responses may not be the best way to send syslog messages. See About Syslog, on page 1103 and Best Practices for Configuring Security Event Syslog Messaging, on page 2261.

Note Alerts that use alert responses are sent by the Firepower Management Center. Intrusion email alerts, which do not use alert responses, are also sent by the Firepower Management Center. By contrast, SNMP and syslog alerts that are based on individual intrusion rules triggering are sent directly by managed devices. For more information, see External Alerting for Intrusion Events, on page 2203.

In most cases, the information in an external alert is the same as the information in any associated event you logged to the database. However, for correlation event alerts where the correlation rule contains a connection

tracker, the information you receive is the same as for an alert on a traffic profile change, regardless of the base event type.

You create and manage alert responses on the Alerts page (**Policies** > **Actions** > **Alerts**). New alert responses are automatically enabled. To temporarily stop alert generation, you can disable alert responses rather than deleting them.

Changes to alert responses take effect immediately, except when sending connection logs to an SNMP trap or syslog server.

In a multidomain deployment, when you create an alert response it belongs to the current domain. This alert response can also be used by descendant domains.

Configurations Supporting Alert Responses

After you create an alert reponse, you can use it to send the following external alerts from the Firepower Management Center.

Alert/Event Type	For More Information
Intrusion events, by impact flag	Configuring Impact Flag Alerting, on page 2199
Discovery events, by type	Configuring Discovery Event Alerting, on page 2200
Malware and retrospective malware events detected by AMP for Networks ("network-based")	Configuring AMP for Networks Alerting, on page 2200
Correlation events, by correlation policy violation	Adding Responses to Rules and White Lists, on page 2109
Connection events, by the logging rule or default action (email alerts not supported)	Other Connections You Can Log, on page 2355
Health events, by health module and severity level	Creating Health Monitor Alerts, on page 310

Requirements and Prerequisites for Alert Responses

Model Support

Any.

Supported Domains

Any

User Roles

- Admin

Creating an SNMP Alert Response

You can create SNMP alert responses using SNMPv1, SNMPv2, or SNMPv3 for an device type except FTD.

Note When selecting SNMP versions for the SNMP protocol, note that SNMPv2 only supports read-only communities and SNMPv3 only supports read-only users. SNMPv3 also supports encryption with AES128.

If you want to monitor 64-bit values with SNMP, you must use SNMPv2 or SNMPv3. SNMPv1 does not support 64-bit monitoring.

Before you begin

- If your network management system requires the Firepower Management Center's management information base (MIB) file, obtain it at `/etc/sf/DCEALERT.MIB`.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create SNMP Alert**.

Step 3 Edit the SNMP Alert Configuration fields:

a) **Name—**Enter a name to identify the SNMP response.

b) **Trap Server—**Enter the hostname or IP address of the SNMP trap server.

Note The system does **not** warn you if you enter an invalid IPv4 address (such as 192.169.1.456) in this field. Instead, the invalid address is treated as a hostname.

c) **Version—**Choose the SNMP version you want to use from the drop-down list. SNMPv3 is the default.

Choose from:

- **SNMPv1** or **SNMPv2**: Enter a read-only SNMP community name in the **Community String** field, then skip to the end of the procedure.

Note Do not include special characters (< > / % # & ? ', etc.) in the SNMP community string name.

- For **SNMPv3**: Enter the name of the user that you want to authenticate with the SNMP server in the **User Name** field and continue to the next step.

d) **Authentication Protocol—**Choose the protocol you want to use to encrypt authentication from the drop-down list.

Choose from:

- **MD5**—Message Digest 5 (MD5) hash function.
- **SHA**—Secure Hash Algorithm (SHA) hash function.

e) **Authentication Password—**Enter the password to enable authentication.

f) **Privacy Protocol—**Choose the protocol you want to use to encrypt a private password from the drop-down list.

Choose from:

- **DES**—Data Encryption Standard (DES) using 56-bit keys in a symmetric secret-key block algorithm.
- **AES**—Advanced Encryption Standard (AES) using 56-bit keys in a symmetric cipher algorithm.
- **AES128**—AES using 128-bit keys in a symmetric cipher algorithm. A longer key provides higher security but a reduction in performance.

g) **Privacy Password—**Enter the privacy password required by the SNMP server. If you specify a private password, privacy is enabled, and you must also specify an authentication password.

h) **Engine ID—**Enter an identifier for the SNMP engine, in hexadecimal notation, using an even number of digits.

When you use SNMPv3, the system uses an Engine ID value to encode the message. Your SNMP server requires this value to decode the message.

Cisco recommends that you use the hexadecimal version of the Firepower Management Center's IP address. For example, if the Firepower Management Center has an IP address of 10.1.1.77, use 0a01014D0.

Step 4 Click **Save**.

What to do next

Changes take effect immediately, EXCEPT:

If you are using alert responses to send connection logs, you must deploy configuration changes after you edit those alert responses.

Creating a Syslog Alert Response

When configuring a syslog alert response, you can specify the severity and facility associated with the syslog messages to ensure that they are processed properly by the syslog server. The facility indicates the subsystem that creates the message and the severity defines the severity of the message. Facilities and severities are not displayed in the actual message that appears in the syslog, but are instead used to tell the system that receives the syslog message how to categorize it.

Tip For more detailed information about how syslog works and how to configure it, refer to the documentation for your system. On UNIX systems, the `man` pages for `syslog` and `syslog.conf` provide conceptual information and configuration instructions.

Although you can choose any type of facility when creating a syslog alert response, you should choose one that makes sense based on your syslog server; not all syslog servers support all facilities. For UNIX syslog servers, the `syslog.conf` file should indicate which facilities are saved to which log files on the server.

Before you begin

- This procedure is not the recommended way to send syslog messages in many cases. For specifics, see Best Practices for Configuring Security Event Syslog Messaging, on page 2261.
- Confirm that the syslog server can accept remote messages.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Syslog Alert**.

Step 3 Enter a **Name** for the alert.

Step 4 In the **Host** field, enter the hostname or IP address of your syslog server.

Note The system does **not** warn you if you enter an invalid IPv4 address (such as 192.168.1.456) in this field. Instead, the invalid address is treated as a hostname.

Step 5 In the **Port** field, enter the port the server uses for syslog messages. By default, this value is 514.

Step 6 From the **Facility** list, choose a facility described in Syslog Alert Facilities, on page 2197.

Step 7 From the **Severity** list, choose a severity described in Syslog Severity Levels, on page 2198.

Step 8 In the **Tag** field, enter the tag name that you want to appear with the syslog message.

For example, if you wanted all messages sent to the syslog to be preceded with `FromMC`, enter `FromMC` in the field.

Step 9 Click **Save**.

What to do next

Changes take effect immediately, EXCEPT:

If you are using alert responses to send connection logs to a syslog server, you must deploy configuration changes after you edit those alert responses.

If you will use this alert response for security events, you MUST specify the alert response in a policy. See Configuration Locations for Security Event Syslogs, on page 2266.

Syslog Alert Facilities

The following table lists the syslog facilities you can select.

Table 268: Available Syslog Facilities

Facility	Description
ALERT	An alert message.
AUDIT	A message generated by the audit subsystem.
AUTH	A message associated with security and authorization.
AUTHPRIV	A restricted access message associated with security and authorization. On many systems, these messages are forwarded to a secure file.
CLOCK	A message generated by the clock daemon. Note that syslog servers running a Windows operating system will use the `CLOCK` facility.

Facility	Description
CRON	A message generated by the clock daemon. Note that syslog servers running a Linux operating system will use the `CRON` facility.
DAEMON	A message generated by a system daemon.
FTP	A message generated by the FTP daemon.
KERN	A message generated by the kernel. On many systems, these messages are printed to the console when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a mail system.
NEWS	A message generated by the network news subsystem.
NTP	A message generated by the NTP daemon.
SYSLOG	A message generated by the syslog daemon.
USER	A message generated by a user-level process.
UUCP	A message generated by the UUCP subsystem.

Syslog Severity Levels

The following table lists the standard syslog severity levels you can select.

Table 269: Syslog Severity Levels

Level	Description
ALERT	A condition that should be corrected immediately.
CRIT	A critical condition.
DEBUG	Messages that contain debugging information.
EMERG	A panic condition broadcast to all users.
ERR	An error condition.
INFO	Informational messages.
NOTICE	Conditions that are not error conditions, but require attention.
WARNING	Warning messages.

Creating an Email Alert Response

Before you begin

- Confirm that the Firepower Management Center can reverse-resolve its own IP address.
- Configure your mail relay host as described in Configuring a Mail Relay Host and Notification Address, on page 1045.

Note You **cannot** use email alerting to log connections.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Email Alert**.

Step 3 Enter a **Name** for the alert response.

Step 4 In the **To** field, enter the email addresses where you want to send alerts, separated by commas.

Step 5 In the **From** field, enter the email address that you want to appear as the sender of the alert.

Step 6 Next to **Relay Host**, verify the listed mail server is the one that you want to use to send the alert.

Tip To change the email server, click **Edit** ( ).

Step 7 Click **Save**.

Configuring Impact Flag Alerting

You can configure the system to alert you whenever an intrusion event with a specific impact flag occurs. Impact flags help you evaluate the impact an intrusion has on your network by correlating intrusion data, network discovery data, and vulnerability information.

You must have the Threat Smart License or Protection Classic License to configure these alerts.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Impact Flag Alerts**.

Step 3 In the **Alerts** section, choose the alert response you want to use for each alert type.

Tip To create a new alert response, choose **New** from any drop-down list.

Step 4 In the **Impact Configuration** section, check the appropriate check boxes to specify the alerts you want to receive for each impact flag.

For definitions of the impact flags, see Intrusion Event Impact Levels, on page 2412.

Step 5 Click **Save**.

Configuring Discovery Event Alerting

You can configure the system to alert you whenever a specific type of discovery event occurs.

Before you begin

- Configure your network discovery policy to log the discovery event types you want to configure alerting for as described in Configuring Network Discovery Event Logging, on page 2087.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Discovery Event Alerts**.

Step 3 In the **Alerts** section, choose the alert response you want to use for each alert type.

Tip To create a new alert response, choose **New** from any drop-down list.

Step 4 In the **Events Configuration** section, check the check boxes that correspond to the alerts you want to receive for each discovery event type.

Step 5 Click **Save**.

Configuring AMP for Networks Alerting

You can configure the system to alert you whenever any malware event, including a retrospective event, is generated by AMP for Networks (that is, a "network-based malware event" is generated.) You cannot alert on malware events generated by AMP for Endpoints ("endpoint-based malware events.")

Before you begin

- Configure a file policy to perform malware cloud lookups and associate that policy with an access control rule as described in Understanding Access Control, on page 1239.
- You must have the Malware license to configure these alerts.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Advanced Malware Protections Alerts**.

Step 3 In the **Alerts** section, choose the alert response you want to use for each alert type.

Tip To create a new alert response, choose **New** from any drop-down list.

Step 4 In the **Event Configuration** section, check the check boxes that correspond to the alerts you want to receive for each malware event type.

Keep in mind that **All network-based malware events** includes **Retrospective Events**.

(By definition, network-based malware events do not include events generated by AMP for Endpoints.)

Step 5 Click **Save**.

CHAPTER 109

External Alerting for Intrusion Events

The following topics describe how to configure external alerting for intrusion events:

About External Alerting for Intrusion Events

External intrusion event notification can help with critical-system monitoring:

- SNMP—Configured per intrusion policy and sent from managed devices. You can enable SNMP alerting per intrusion rule.
- Syslog—Configured per intrusion policy and sent from managed devices. When you enable syslog alerting in an intrusion policy, you turn it on for every rule in the policy.
- Email—Configured across all intrusion policies and sent from the Firepower Management Center. You can enable email alerts per intrusion rule, as well as limit their length and frequency.

Keep in mind that if you configured intrusion event suppression or thresholding, the system may not generate intrusion events (and thus may not send alerts) every time a rule triggers.

In a multidomain deployment, you can configure external alerting in any domain. In ancestor domains, the system generates notifications for intrusion events in descendant domains.

Note The Firepower Management Center also uses SNMP, syslog, and email *alert responses* to send different types of external alerts; see Firepower Management Center Alert Responses, on page 2193. The system does **not** use alert responses to send alerts based on individual intrusion events.

Configuring SNMP Alerting for Intrusion Events

After you enable external SNMP alerting in an intrusion policy, you can configure individual rules to send SNMP alerts when they trigger. These alerts are sent from the managed device.

Step 1 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 2 Make sure **SNMP Alerting** is **Enabled**, then click **Edit**.
A message at the bottom of the page identifies the intrusion policy layer that contains the configuration.

Step 3 Choose an **SNMP Version**, then specify configuration options as described in Intrusion SNMP Alert Options, on page 2205.

Step 4 In the navigation pane, click **Rules**.

Step 5 In the rules pane, choose the rules where you want to set SNMP alerts, then choose **Alerting** > **Add SNMP Alert**.

Step 6 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Intrusion SNMP Alert Options

If your network management system requires a management information base file (MIB), you can obtain it from the Firepower Management Center at `/etc/sf/DCEALERT.MIB`.

SNMP v2 Options

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.
Trap Server	The server that will receive SNMP traps notification. You can specify a single IP address or hostname.
Community String	The community name.

SNMP v3 Options

Managed devices encode SNMPv3 alerts with an Engine ID value. To decode the alerts, your SNMP server requires this value, which is the hexadecimal version of the sending device's management interface IP address, appended with "01."

For example, if the device sending the SNMP alert has a management interface IP address of 172.16.1.50, the Engine ID value is 0xAC10013201.

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.
Trap Server	The server that will receive SNMP traps notification. You can specify a single IP address or hostname.

Option	Description
Authentication Password	The password required for authentication. SNMP v3 uses either the Message Digest 5 (MD5) hash function or the Secure Hash Algorithm (SHA) hash function to encrypt this password, depending on configuration. If you specify an authentication password, authentication is enabled.
Private Password	The SNMP key for privacy. SNMP v3 uses the Data Encryption Standard (DES) block cipher to encrypt this password. When you enter an SNMP v3 password, the password displays in plain text during initial configuration but is saved in encrypted format. If you specify a private password, privacy is enabled, and you must also specify an authentication password.
User Name	Your SNMP user name.

Configuring Syslog Alerting for Intrusion Events

After you enable syslog alerting in an intrusion policy, the system sends all intrusion events to the syslog, either on the managed device itself or to an external host or hosts. If you specify an external host, syslog alerts are sent from the managed device.

Step 1 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 2 Make sure **Syslog Alerting** is **Enabled**, then click **Edit**.
A message at the bottom of the page identifies the intrusion policy layer that contains the configuration. The **Syslog Alerting** page is added under **Advanced Settings**.

Step 3 Enter the IP addresses of the **Logging Hosts** where you want to send syslog alerts.

If you leave the **Logging Hosts** field blank, the logging hosts details are taken from Logging in the associated Access Control Policy.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

Step 4 Choose **Facility** and **Severity** levels as described in Facilities and Severities for Intrusion Syslog Alerts, on page 2207.

Step 5 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Facilities and Severities for Intrusion Syslog Alerts

Managed devices can send intrusion events as syslog alerts using a particular facility and **Severity**, so that the logging host can categorize the alerts. The *facility* specifies the subsystem that generated it. These facility and **Severity** values do not appear in the actual syslog messages.

Choose values that make sense based on your environment. Local configuration files (such as syslog.conf on UNIX-based logging hosts) may indicate which facilities are saved to which log files.

Syslog Alert Facilities

Facility	Description
AUTH	A message associated with security and authorization.
AUTHPRIV	A restricted access message associated with security and authorization. On many systems, these messages are forwarded to a secure file.
CRON	A message generated by the clock daemon.
DAEMON	A message generated by a system daemon.
FTP	A message generated by the FTP daemon.
KERN	A message generated by the kernel. On many systems, these messages are printed to the console when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a mail system.
NEWS	A message generated by the network news subsystem.
SYSLOG	A message generated by the syslog daemon.
USER	A message generated by a user-level process.
UUCP	A message generated by the UUCP subsystem.

Syslog Alert Severities

Level	Description
EMERG	A panic condition broadcast to all users
ALERT	A condition that should be corrected immediately
CRIT	A critical condition
ERR	An error condition
WARNING	Warning messages

Level	Description
NOTICE	Conditions that are not error conditions, but require attention
INFO	Informational messages
DEBUG	Messages that contain debug information

Configuring Email Alerting for Intrusion Events

If you enable intrusion email alerting, the system can send email when it generates an intrusion event, regardless of which managed device or intrusion policy detected the intrusion. These alerts are sent from the Firepower Management Center.

Before you begin

- Configure your mail host to receive email alerts; see Configuring a Mail Relay Host and Notification Address, on page 1045.
- Ensure that the Firepower Management Center can reverse resolve is own IP address.

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Intrusion Email**.

Step 3 Choose alerting options, including the intrusion rules or rule groups for which you want to alert, as described in Intrusion Email Alert Options, on page 2208.

Step 4 Click **Save**.

Intrusion Email Alert Options

On/Off

Enables or disables intrusion email alerts.

Note Enabling it will enable alerting for all rules unless individual rules are selected.

From/To Addresses

The email sender and recipients. You can specify a comma-separated list of recipients.

Max Alerts and Frequency

The maximum number of email alerts (**Max Alerts**) that the Firepower Management Center will send per time interval (**Frequency**).

Coalesce Alerts

Reduces the number of alerts sent by grouping alerts that have the same source IP and rule ID.

Summary Output

Enables brief alerts, suitable for text-limited devices. Brief alerts contain:

- Timestamp
- Protocol
- Source and destination IPs and ports
- Message
- The number of intrusion events generated against the same source IP

For example: `2011-05-18 10:35:10 10.1.1.100 icmp 10.10.10.1:8 -> 10.2.1.3:0 snort_decoder: Unknown Datagram decoding problem! (116:108)`

If you enable **Summary Output**, also consider enabling **Coalesce Alerts**. You may also want to lower **Max Alerts** to avoid exceeding text-message limits.

Time Zone

The time zone for alert timestamps.

Email Alerting on Specific Rules Configuration

Allows you to choose the rules where you want to set email alerts.

PART XXIII

Event and Asset Analysis Tools

CHAPTER 110

Using the Context Explorer

The following topics describe how to use the Context Explorer in the Firepower System:

About the Context Explorer

The Firepower System Context Explorer displays detailed, interactive graphical information in context about the status of your monitored network, including data on applications, application statistics, connections, geolocation, indications of compromise, intrusion events, hosts, servers, Security Intelligence, users, files (including malware files), and relevant URLs. Distinct sections present this data in the form of vivid line, bar, pie, and donut graphs, accompanied by detailed lists. The first section, a line chart of traffic and event counts over time, provides an at-a-glance picture of recent trends in your network's activity.

You can easily create and apply custom filters to fine-tune your analysis, and you can examine data sections in more detail by simply clicking or hovering your cursor over graph areas. You can also configure the explorer's time range to reflect a period as short as the last hour or as long as the last year. Only users with the Administrator, Security Analyst, or Security Analyst (Read Only) user roles have access to the Context Explorer.

The Firepower System dashboard is highly customizable and compartmentalized and updates in real time. In contrast, the Context Explorer is manually updated, designed to provide broader context for its data, and has a single, consistent layout designed for active user exploration.

You use the dashboard to monitor real-time activity on your network and appliances according to your own specific needs. Conversely, you use the Context Explorer to investigate a predefined set of recent data in granular detail and clear context: for example, if you notice that only 15% of hosts on your network use Linux, but account for almost all YouTube traffic, you can quickly apply filters to view data only for Linux hosts, only for YouTube-associated application data, or both. Unlike the compact, narrowly focused dashboard widgets, the Context Explorer sections are designed to provide striking visual representations of system activity in a format useful to both expert and casual users of the Firepower System.

The data displayed depends on such factors as how you license and deploy your managed devices, and whether you configure features that provide the data. You can also apply filters to constrain the data that appears in all Context Explorer sections.

In a multidomain deployment, the Context Explorer displays aggregated data from all subdomains when you view it in an ancestor domain. In a leaf domain, you can view data specific to that domain only.

Differences Between the Dashboard and the Context Explorer

The following table summarizes some of the key differences between the dashboard and the Context Explorer.

Table 270: Comparison: Dashboard and Context Explorer

Feature	Dashboard	Context Explorer
Displayable data	Anything monitored by the Firepower System	Applications, application statistics, geolocation, host indications of compromise, intrusion events, files (including malware files), hosts, Security Intelligence events, servers, users, and URLs
Customizability	• Selection of widgets for a dashboard is customizable • Individual widgets can be customized to varying degrees	• Cannot change base layout • Applied filters appear in explorer URL and can be bookmarked for later use
Data update frequency	Automatic (default); user-configured	Manual
Data filtering	Possible for some widgets (must edit widget preferences)	Possible for all parts of the explorer, with support for multiple filters
Graphical context	Some widgets (particularly Custom Analysis) can display data in graph form	Extensive graphical context for all data, including uniquely detailed donut graphs
Links to relevant web interface pages	In some widgets	In every section
Time range of displayed data	User-configured	User-configured

Related Topics

About Dashboards, on page 275

The Traffic and Intrusion Event Counts Time Graph

At the top of the Context Explorer is a line chart of traffic and intrusion events over time. The X-axis plots time intervals (which range from five minutes to one month, depending on the selected time window). The Y-axis plots traffic in kilobytes (blue line) and intrusion event count (red line).

Note that the smallest X-axis interval is five minutes. To accommodate this, the system will round the beginning and ending points in your selected time range down to the nearest five-minute interval.

By default, this section shows all network traffic and all generated intrusion events for the selected time range. If you apply filters, the chart changes to display only traffic and intrusion events associated with the criteria specified in the filters. For example, filtering on the **OS Name** of `Windows` causes the time graph to display only traffic and events associated with hosts using Windows operating systems.

If you filter the Context Explorer on intrusion event data (such as a **Priority** of `High`), the blue Traffic line is hidden to allow greater focus on intrusion events alone.

You can hover your pointer over any point on the graph lines to view exact information about traffic and event counts. Hovering your pointer over one of the colored lines also brings that line to the forefront of the graph, providing clearer context.

This section draws data primarily from the Intrusion Events and Connection Events tables.

The Indications of Compromise Section

The Indications of Compromise (IOC) section of the Context Explorer contains two interactive sections that provide an overall picture of potentially compromised hosts on your monitored network: a proportional view of the most prevalent IOC types triggered, as well as a view of hosts by number of triggered indications.

For more information about IOCs, see Indications of Compromise Data, on page 2529.

The Hosts by Indication Graph

The Hosts by Indication graph, in donut form, displays a proportional view of the Indications of Compromise (IOC) triggered by hosts on your monitored network. The inner ring divides by IOC category (such as `CnC Connected` or `Malware Detected`), while the outer ring further divides that data by specific event type (such as `Impact 2 Intrusion Event — attempted-admin` or `Threat Detected in File Transfer`).

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Hosts and Host Indications of Compromise tables.

The Indications by Host Graph

The Indications by Host graph, in bar form, displays counts of unique Indications of Compromise (IOC) triggered by the 15 most IOC-active hosts on your monitored network.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Hosts and Host Indications of Compromise tables.

The Network Information Section

The Network Information section of the Context Explorer contains six interactive graphs that display an overall picture of connection traffic on your monitored network: sources, destinations, users, and security zones associated with traffic, a breakdown of operating systems used by hosts on the network, as well as a proportional view of access control actions your Firepower System has performed on network traffic.

The Operating Systems Graph

The Operating Systems graph, in donut form, displays a proportional representation of operating systems detected on hosts on your monitored network. The inner ring divides by OS name (such as `Windows` or `Linux`),

while the outer ring further divides that data by specific operating system version (such as `Windows Server 2008` or `Linux 11.x`). Some closely related operating systems (such as Windows 2000, Windows XP, and Windows Server 2003) are grouped together. Very scarce or unrecognized operating systems are grouped under **Other**.

Note that this graph reflects all available data regardless of date and time constraints. If you change the explorer time range, the graph does not change.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Hosts table.

The Traffic by Source IP Graph

The Traffic by Source IP graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top 15 most active source IP addresses on your monitored network. For each source IP address listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note If you filter on intrusion event information, the Traffic by Source IP graph is hidden.

This graph draws data primarily from the Connection Events table.

The Traffic by Source User Graph

The Traffic by Source User graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top 15 most active source users on your monitored network. For each source IP address listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note If you filter on intrusion event information, the Traffic by Source User graph is hidden.

This graph draws data primarily from the Connection Events table. It displays authoritative user data.

The Connections by Access Control Action Graph

The Connections by Access Control Action graph, in pie form, displays a proportional view of access control actions (such as `Block` or `Allow`) that your Firepower System deployment has taken on monitored traffic.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note If you filter on intrusion event information, the Traffic by Source User graph is hidden.

This graph draws data primarily from the Connection Events table.

The Traffic by Destination IP Graph

The Traffic by Destination IP graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top 15 most active destination IP addresses on your monitored network. For each destination IP address listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note If you filter on intrusion event information, the Traffic by Destination IP graph is hidden.

This graph draws data primarily from the Connection Events table.

The Traffic by Ingress/Egress Security Zone Graph

The Traffic by Ingress/Egress Security Zone graph, in bar form, displays counts of incoming or outgoing network traffic (in kilobytes per second) and unique connections for each security zone configured on your monitored network. You can configure this graph to display either ingress (the default) or egress security zone information, according to your needs.

For each security zone listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information

Tip To constrain the graph so it displays only traffic by egress security zone, hover your pointer over the graph, then click **Egress** on the toggle button that appears. Click **Ingress** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Ingress view.

Note If you filter on intrusion event information, the Traffic by Ingress/Egress Security Zone graph is hidden.

This graph draws data primarily from the Connection Events table.

The Application Information Section

The Application Information section of the Context Explorer contains three interactive graphs and one table-format list that display an overall picture of application activity on your monitored network: traffic, intrusion events, and hosts associated with applications, further organized by the estimated risk or business relevance assigned to each application. The Application Details list provides an interactive list of each application and its risk, business relevance, category, and host count.

For all instances of "application" in this section, the Application Information graph set, by default, specifically examines application protocols (such as DNS or SSH). You can also configure the Application Information section to specifically examine client applications (such as PuTTY or Firefox) or web applications (such as Facebook or Pandora).

Focusing the Application Information Section

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 Hover your pointer over the **Application Protocol Information** section.

Note If you previously changed this setting in the same Context Explorer session, the section title may appear as **Client Application Information** or **Web Application Information** instead.

Step 3 Click **Application Protocol**, **Client Application**, or **Web Application**.

The Traffic by Risk/Business Relevance and Application Graph

The Traffic by Risk/Business Relevance and Application graph, in donut form, displays a proportional representation of application traffic detected on your monitored network, arranged by the applications' estimated risk (the default) or estimated business relevance. The inner ring divides by estimated risk/business relevance level (such as `Medium` or `High`), while the outer ring further divides that data by specific application (such as `SSH` or `NetBIOS`). Scarcely detected applications are grouped under **Other**.

Note that this graph reflects all available data regardless of date and time constraints. If you change the explorer time range, the graph does not change.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays traffic by business relevance and application, hover your pointer over the graph, then click **Business Relevance** on the toggle button that appears. Click **Risk** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Risk view.

Note If you filter on intrusion event information, the Traffic by Risk/Business and Application graph is hidden.

This graph draws data primarily from the Connection Events and Application Statistics tables.

The Intrusion Events by Risk/Business Relevance and Application Graph

The Intrusion Events by Risk/Business Relevance and Application graph, in donut form, displays a proportional representation of intrusion events detected on your monitored network and the applications associated with those events, arranged by the applications' estimated risk (the default) or estimated business relevance. The inner ring divides by estimated risk/business relevance level (such as `Medium` or `High`), while the outer ring further divides that data by specific application (such as `SSH` or `NetBIOS`). Scarcely detected applications are grouped under **Other**.

Hover your pointer over any part of the donut graph to view more detailed information. Click any part of the graph to filter or drill down on that information, or (where applicable) to view application information.

Tip To constrain the graph so it displays intrusion events by business relevance and application, hover your pointer over the graph, then click **Business Relevance** on the toggle button that appears. Click **Risk** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Risk view.

This graph draws data primarily from the Intrusion Events and Application Statistics tables.

The Hosts by Risk/Business Relevance and Application Graph

The Hosts by Risk/Business Relevance and Application graph, in donut form, displays a proportional representation of hosts detected on your monitored network and the applications associated with those hosts, arranged by the applications' estimated risk (the default) or estimated business relevance. The inner ring divides by estimated risk/business relevance level (such as `Medium` or `High`), while the outer ring further divides that data by specific application (such as `SSH` or `NetBIOS`). Very scarce applications are grouped under **Other**.

Hover your pointer over any part of the donut graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays hosts by business relevance and application, hover your pointer over the graph, then click **Business Relevance** on the toggle button that appears. Click **Risk** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Risk view.

This graph draws data primarily from the Applications table.

The Application Details List

At the bottom of the Application Information section is the Application Details List, a table that provides estimated risk, estimated business relevance, category, and hosts count information for each application detected on your monitored network. The applications are listed in descending order of associated host count.

The Application Details List table is not sortable, but you can click on any table entry to filter or drill down on that information, or (where applicable) to view application information. This table draws data primarily from the Applications table.

Note that this list reflects all available data regardless of date and time constraints. If you change the explorer time range, the list does not change.

The Security Intelligence Section

The Security Intelligence section of the Context Explorer contains three interactive bar graphs that display an overall picture of traffic on your monitored network that is blocked or monitored by Security Intelligence. The graphs sort such traffic by category, source IP address, and destination IP address, respectively; both the amount of traffic (in kilobytes per second) and the number of applicable connections appear.

The Security Intelligence Traffic by Category Graph

The Security Intelligence Traffic by Category graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top Security Intelligence categories of traffic on your monitored network. For each category listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Security Intelligence Traffic by Category graph is hidden.

This graph draws data primarily from the Security Intelligence Events table.

The Security Intelligence Traffic by Source IP Graph

The Security Intelligence Traffic by Source IP graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top source IP addresses of Security Intelligence-monitored traffic on your monitored network. For each category listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Security Intelligence Traffic by Source IP graph is hidden.

This graph draws data primarily from the Security Intelligence Events table.

The Security Intelligence Traffic by Destination IP Graph

The Security Intelligence Traffic by Destination IP graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top destination IP addresses of Security Intelligence-monitored traffic on your monitored network. For each category listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Security Intelligence Traffic by Destination IP graph is hidden.

This graph draws data primarily from the Security Intelligence Events table.

The Intrusion Information Section

The Intrusion Information section of the Context Explorer contains six interactive graphs and one table-format list that display an overall picture of intrusion events on your monitored network: impact levels, attack sources, target destinations, users, priority levels, and security zones associated with intrusion events, as well as a detailed list of intrusion event classifications, priorities, and counts.

The Intrusion Events by Impact Graph

The Intrusion Events by Impact graph, in pie form, displays a proportional view of intrusion events on your monitored network, grouped by estimated impact level (from 0 to 4).

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the intrusion detection (IDS Statistics) and Intrusion Events tables.

The Top Attackers Graph

The Top Attackers graph, in bar form, displays counts of intrusion events for the top attacking host IP addresses (causing those events) on your monitored network.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Intrusion Events table.

The Top Users Graph

The Top Users graph, in bar form, displays users on your monitored network that are associated with the highest intrusion event counts, by event count.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the intrusion detection (IDS) User Statistics and Intrusion Events tables. It displays authoritative user data.

The Intrusion Events by Priority Graph

The Intrusion Events by Priority graph, in pie form, displays a proportional view of intrusion events on your monitored network, grouped by estimated priority level (such as `High`, `Medium`, or `Low`).

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Intrusion Events table.

The Top Targets Graph

The Top Targets graph, in bar form, displays counts of intrusion events for the top target host IP addresses (targeted in the connections causing those events) on your monitored network.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

This graph draws data primarily from the Intrusion Events table.

The Top Ingress/Egress Security Zones Graph

The Top Ingress/Egress Security Zones graph, in bar form, displays counts of intrusion events associated with each security zone (ingress or egress, depending on graph settings) configured on your monitored network.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only traffic by egress security zone, hover your pointer over the graph, then click **Egress** on the toggle button that appears. Click **Ingress** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Ingress view.

This graph draws data primarily from the Intrusion Events table.

You can configure this graph to display either ingress (the default) or egress security zone information, according to your needs.

The Intrusion Event Details List

At the bottom of the Intrusion Information section is the Intrusion Event Details List, a table that provides classification, estimated priority, and event count information for each intrusion event detected on your monitored network. The events are listed in descending order of event count.

The Intrusion Event Details List table is not sortable, but you can click on any table entry to filter or drill down on that information. This table draws data primarily from the Intrusion Events table.

The Files Information Section

The Files Information section of the Context Explorer contains six interactive graphs that display an overall picture of file and malware events on your monitored network.

Five of the graphs display data related to AMP for Networks (formerly called AMP for Firepower): the file types, file names, and malware dispositions of the files detected in network traffic, as well as the hosts sending (uploading) and receiving (downloading) those files. The final graph displays all malware threats detected in your organization, whether by AMP for Networks or AMP for Endpoints.

Note If you filter on intrusion information, the entire Files Information Section is hidden.

The Top File Types Graph

The Top File Types graph, in donut form, displays a proportional view of the file types detected in network traffic (outer ring), grouped by file category (inner ring).

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events table.

The Top File Names Graph

The Top File Names graph, in bar form, displays counts of the top unique file names detected in network traffic.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events table.

The Files by Disposition Graph

The Top File Types graph, in pie form, displays a proportional view of the malware dispositions for files detected by the AMP for Networks feature (formerly called AMP for Firepower). Note that only files for which the Firepower Management Center performed a malware cloud lookup have dispositions. Files that did not trigger a cloud lookup have a disposition of `N/A`. The disposition `Unavailable` indicates that the Firepower Management Center could not perform a malware cloud lookup.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events table.

The Top Hosts Sending Files Graph

The Top Hosts Sending Files graph, in bar form, displays counts of the number of files detected in network traffic for the top file-sending host IP addresses.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only hosts sending malware, hover your pointer over the graph, then click **Malware** on the toggle button that appears. Click **Files** to return to the default files view. Note that navigating away from the Context Explorer also returns the graph to the default files view.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events table.

The Top Hosts Receiving Files Graph

The Top Hosts Receiving Files graph, in bar form, displays counts of the number of files detected in network traffic for the top file-receiving host IP addresses.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only hosts receiving malware, hover your pointer over the graph, then click **Malware** on the toggle button that appears. Click **Files** to return to the default files view. Note that navigating away from the Context Explorer also returns the graph to the default files view.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events table.

The Top Malware Detections Graph

The Top Malware Detections graph, in bar form, displays counts of the top malware threats detected in your organization, whether by AMP for Networks or AMP for Endpoints.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Note that you must have a Malware license to for this graph to display AMP for Networks data.

This graph draws data primarily from the File Events and Malware Events tables.

The Geolocation Information Section

The Geolocation Information section of the Context Explorer contains three interactive donut graphs that display an overall picture of countries with which hosts on your monitored network are exchanging data: unique connections by initiator or responder country, intrusion events by source or destination country, and file events by sending or receiving country.

The Connections by Initiator/Responder Country Graph

The Connections by Initiator/Responder Country graph, in donut form, displays a proportional view of the countries involved in connections on your network as either the initiator (the default) or the responder. The inner ring groups these countries together by continent.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only countries acting as the responder in connections, hover your pointer over the graph, then click **Responder** on the toggle button that appears. Click **Initiator** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Initiator view.

This graph draws data primarily from the Connection Summary Data table.

The Intrusion Events by Source/Destination Country Graph

The Intrusion Events by Source/Destination Country graph, in donut form, displays a proportional view of the countries involved in intrusion events on your network as either the source of the event (the default) or the destination. The inner ring groups these countries together by continent.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only countries acting as the destinations of intrusion events, hover your pointer over the graph, then click **Destination** on the toggle button that appears. Click **Source** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Source view.

This graph draws data primarily from the Intrusion Events table.

The File Events by Sending/Receiving Country Graph

The File Events by Sending/Receiving Country graph, in donut form, displays a proportional view of the countries detected in file events on your network as either sending (the default) or receiving files. The inner ring groups these countries together by continent.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to filter or drill down on that information.

Tip To constrain the graph so it displays only countries receiving files, hover your pointer over the graph, then click **Receiver** on the toggle button that appears. Click **Sender** to return to the default view. Note that navigating away from the Context Explorer also returns the graph to the default Sender view.

This graph draws data primarily from the File Events table.

The URL Information Section

The URL Information section of the Context Explorer contains three interactive bar graphs that display an overall picture of URLs with which hosts on your monitored network are exchanging data: traffic and unique connections associated with URLs, sorted by individual URL, URL category, and URL reputation. You cannot filter on URL information.

Note If you filter on intrusion event information, the entire URL Information Section is hidden.

Note that you must have a URL Filtering license for this graph to include URL category and reputation data.

The Traffic by URL Graph

The Traffic by URL graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the top 15 most requested URLs on your monitored network. For each URL listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Traffic by URL graph is hidden.

Note that you must have a URL Filtering license for this graph to include URL category and reputation data.

This graph draws data primarily from the Connection Events table.

The Traffic by URL Category Graph

The Traffic by URL Category graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the most requested URL categories (such as `Search Engines` or `Streaming Media`) on your monitored network. For each URL category listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Traffic by URL Category graph is hidden.

Note that you must have a URL Filtering license for this graph to include URL category and reputation data.

This graph draws data primarily from the URL Statistics and Connection Events tables.

The Traffic by URL Reputation Graph

The Traffic by URL Reputation graph, in bar form, displays counts of network traffic (in kilobytes per second) and unique connections for the most requested URL reputation groups (such as Trusted or Neutral) on your monitored network. For each URL reputation listed, blue bars represent traffic data and red bars represent connection data.

Hover your pointer over any part of the graph to view more detailed information. Click any part of the graph to drill down on that information.

Note If you filter on intrusion event information, the Traffic by URL Reputation graph is hidden.

Note that you must have a URL Filtering license for this graph to include URL category and reputation data.

This graph draws data primarily from the URL Statistics and Connection Events tables.

Requirements and Prerequisites for the Context Explorer

Model Support

Any.

Supported Domains

Any

User Roles

- Admin
- Security Analyst

Refreshing the Context Explorer

The Context Explorer does not automatically update the information it displays. To incorporate new data, you must manually refresh the explorer.

Note that, although reloading the Context Explorer itself (by refreshing the browser program or navigating away from, then back to, the Context Explorer) refreshes all displayed information, this does not preserve any changes you made to section configuration (such as the Ingress/Egress graphs and the Application Information section) and may cause delays in loading.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 Click **Reload** at the upper right.

Reload is dimmed until your refresh is finished.

Setting the Context Explorer Time Range

You can configure the Context Explorer time range to reflect a period as short as the last hour (the default) or as long as the last year. Note that when you change the time range, the Context Explorer does not automatically update to reflect the change. To apply the new time range, you must manually refresh the explorer.

Changes to the time range persist even if you navigate away from the Context Explorer or end your login session.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 From the **Show the last** drop-down list, choose a time range.

Step 3 Optionally, to view data from the new time range, click **Reload**.

Tip Clicking **Apply Filters** also applies any time range updates.

Minimizing and Maximizing Context Explorer Sections

You can minimize and hide one or more sections of the Context Explorer. This is useful if you want to focus on only certain sections, or if you want a simpler view. You cannot minimize the Traffic and Intrusion Event Counts Time Graph.

Context Explorer sections retain the minimized or maximized states that you configure even if you refresh the page or log out of the appliance.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 To minimize a section, click **Minimize** (⁻) in a section's title bar.

Step 3 To maximize a section, click maximize **Maximize** (□) in a minimized section's title bar.

Drilling Down on Context Explorer Data

If you want to examine graph or list data in more detail than the Context Explorer allows, you can drill down to the table views of the relevant data. (Note that you cannot drill down on the Traffic and Intrusion Events over Time graph.) For example, drilling down on an IP address in the Traffic by Source IP graph displays the Connections with Application Details view of the Connection Events table, including only data associated with the source IP address you selected.

Depending on the type of data you examine, additional options can appear in the context menu. Data points that are associated with specific IP addresses offer the option to view host or whois information on the IP address you select. Data points associated with specific applications offer the option to view application information on the application you select. Data points associated with a specific user offer the option to view that user's user profile page. Data points associated with an intrusion event message offer the option to view the rule documentation for that event's associated intrusion rule, and data points associated with a specific IP address offer the option to add that address to a Block or Do Not Block list. For more information about these lists, see Global and Domain Security Intelligence Lists, on page 459 and subtopics.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 In any section but **Traffic and Intrusion Events over Time**, click a data point that you want to investigate.

Step 3 Depending on the data point you selected, you have several options:

- To view more details of this data in a table view, choose **Drill into Analysis**.
- If you chose a data point associated with a specific IP address and want more information about the associated host, choose **View Host Information**.
- If you chose a data point with a specific IP address and want to make a whois search on that address, choose **Whois**.
- If you chose a data point associated with a specific application and want more information about that application, choose **View Application Information**.
- If you chose a data point associated with a specific user and want more information about that user, choose **View User Information**.
- If you chose a data point associated with a specific intrusion event message and want more information about the associated intrusion rule, choose **View Rule Documentation**; optionally, then click **Rule Documentation** to view more-specific rule details
- If you chose a data point associated with a specific IP address and want to add that IP address to the Security Intelligence global Block or Do Not Block list, choose the appropriate option.

Filters in the Context Explorer

Beyond the basic, wide-ranging data that the Context Explorer initially displays, you have the option to filter that data for a more granular contextual picture of activity on your network. Filters encompass all types of Firepower System data except URL information, support exclusion as well as inclusion, can be applied quickly by clicking on Context Explorer graph data points, and affect the entire explorer. You can apply up to 20 filters at a time.

You can add filters to Context Explorer data in several ways:

- from the Add Filter dialog
- from the context menu, when you select a data point in the explorer
- from the text links that appear in certain detail view pages (Application Detail, Host Profile, Rule Detail, and User Profile). Clicking these links automatically opens and filters the Context Explorer according to the relevant data on the detail view page. For example, clicking the Context Explorer link on a user detail page for the user `jenkins` constrains the explorer to show only data associated with that user

Some filter types are incompatible with others: for example, filters that relate to intrusion events (such as **Device** and **Inline Result**) cannot be applied at the same time as connection event-related filters (such as **Access Control Action**) because the system cannot sort connection event data by intrusion event data. The system automatically prevents incompatible filters from simultaneously applying; when one filter type is more recently activated, filters of the incompatible type are hidden as long as the incompatibility exists.

When multiple filters are active, values for the same data type are treated as OR search criteria: all data that matches at least one of the values appears. Values for different data types are treated as AND search criteria: to appear, data must match at least one value for each filtered data type. For example, data that appears for the filter set of `Application: 2channel`, `Application: Reddit`, and `User: edickinson` must be associated with the user `edickinson` **AND** either the application `2channel` **OR** the application `Reddit`.

In a multidomain deployment, you can filter by multiple descendant domains when viewing the Context Explorer in an ancestor domain. In such cases, use caution when also adding **IP Address** filters. The system builds a separate network map for each leaf domain. Using literal IP addresses to constrain this configuration can have unexpected results.

Note that the data displayed depends on such factors as how you license and deploy your managed devices and whether you configure features that provide the data.

Note Filters function as a simple, agile tool to get the precise Firepower data context you need at any given time. They are not intended as permanent configuration settings, and disappear when you navigate away from the Context Explorer or end your session. To preserve filter settings for later use, see Saving Filtered Context Explorer Views, on page 2233.

Data Type Field Options

The following table lists the data types available as filters, with examples and brief definitions of each.

Table 271: Filter Data Types

Type	Example Values	Definition
Access Control Action	`Allow`, `Block`	Action taken by your access control policy to allow or block traffic.
Application Category	`web browser`, `email`	General classification of an application's most essential function.
Application Name	`Facebook`, `HTTP`	Name of an application.
Application Risk	`Very High`, `Medium`	Estimated security risk of an application.
Application Tag	`encrypts communications`, `sends mail`	Additional information about an application; applications can have any number of tags, including none.
Application Type	`Client`, `Web Application`	Type of an application: application protocol, client, or web application.
Business Relevance	`Very Low`, `High`	Estimated relevance of an application to business activity (as opposed to recreation).
Continent	`North America`, `Asia`	Continent associated with a routable IP address detected on your monitored network.
Country	`Canada`, `Japan`	Country associated with a routable IP address detected on your monitored network.
Device	`device1.example.com`, `192.168.1.3`	Name or IP address of a device on your monitored network.
Domain	`Asia Division`, `Europe Division`	The domain of the device whose network activity you want to graph. This data type is only present in a multidomain deployment.
Event Classification	`Potential Corporate Policy Violation`, `Attempted Denial of Service`	Capsule description of an intrusion event, determined by the classification of the rule, decoder, or preprocessor that triggered it.
Event Message	`dns response`, `P2P`	Message generated by an event, determined by the rule, decoder, or preprocessor that triggered it.
File Disposition	`Malware`, `Clean`	Disposition of a file for which the Firepower Management Center performed a malware cloud lookup.
File Name	`Packages.bz2`	Name of a file detected in network traffic.

Type	Example Values	Definition
File SHA256	any 32-bit string	SHA-256 hash value of a file for which the Firepower Management Center performed a malware cloud lookup.
File Type	`GZ`, `SWF`, `MOV`	File type detected in network traffic.
File Type Category	`Archive`, `Multimedia`, `Executables`	General category of file type detected in network traffic.
IP Address	`192.168.1.3`, `2001:0db8:85a3::0000/24`	IPv4 or IPv6 addresses, address ranges, or address blocks. Note that searching for an IP address returns events where that address was either the source or the destination for the event.
Impact Level	`Impact Level 1`, `Impact Level 2`	Estimated impact of an event on your monitored network.
Inline Result	`dropped`, `would have dropped`	Whether traffic was dropped, would have been dropped, or was not acted upon by the system.
IOC Category	`High Impact Attack`, `Malware Detected`	Category for a triggered Indication of Compromise (IOC) event.
IOC Event Type	`exploit-kit`, `malware-backdoor`	Identifier associated with a specific Indication of Compromise (IOC), referring to the event that triggers it.
Malware Threat Name	`W32.Trojan.a6b1`	The name of a malware threat.
OS Name	`Windows`, `Linux`	Name of an operating system.
OS Version	`XP`, `2.6`	Specific version of an operating system.
Priority	`high`, `low`	Estimated urgency of an event.
Security Intelligence Category	`Malware`, `Spam`	Category of risky traffic, as determined by Security Intelligence.
Security Zone	`My Security Zone`, `Security Zone X`	A set of interfaces through which traffic is analyzed and, in an inline deployment, passes.
SSL	`yes, no`	SSL- or TLS-encrypted traffic.
User	`wsmith`, `mtwain`	Identity of a user logged in to a host on your monitored network.

Creating a Filter from the Add Filter Window

Use this procedure to create filters from scratch with the Add Filter window. (You can also use the context menu to create quick filters.)

The Add Filter window, which you access by clicking **Plus** (+) under **Filters** at the top left of the Context Explorer, contains only two fields:

- The **Data Type** drop-down list contains many different types of Firepower System data you can use to constrain the Context Explorer. After you select a data type, you then enter a specific value for that type in the **Filter** field (for example, a value of `Asia` for the type **Continent**). To assist you, the Filter field presents several grayed-out example values for the data type you select. (These are erased when you enter data in the field.)
- In the **Filter** field, you can input special search parameters such as `*` and `!` essentially as you can in event searches. You can create exclusionary filters by prefixing filter parameters with the `!` symbol.

Note Filters that you add are not automatically applied; you must click **Apply Filters** to see the filtering in the Context Explorer.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 Under **Filters** at the top left, click **Plus** (+).

Step 3 From the **Data Type** drop-down list, choose the data type you want to filter on.

Step 4 In the **Filter** field, enter the data type value you want to filter on.

Step 5 Click **OK**.

Step 6 Optionally, repeat the previous steps to add more filters until you have the filter set you need.

Step 7 Click **Apply Filters**.

Data Type Field Options, on page 2229
Search Constraints, on page 2323

Creating a Quick Filter from the Context Menu

While exploring Context Explorer graph and list data, you can click on data points, then use the context menu to quickly create a filter based on that data, either inclusive or exclusive. If you use the context menu to filter on information of data type Application, User, or Intrusion Event Message, or any individual host, the filter widget includes a widget information that links to the relevant detail page for that data type (such as Application Detail for application data). Note that you cannot filter on URL data.

You can also use the context menu to investigate specific graph or list data in more detail.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 In any explorer section except Traffic and Intrusion Events over Time or sections that contain URL data, click a data point you want to filter on.

Step 3 You have two options:

- To add a filter for this data, click **Add Filter**.
- To add an exclusion filter for this data, click **Add Exclude Filter**. The filter, when applied, displays all data **not** associated with the excluded value. Exclude filters display an exclamation point (!) before the filter value.

Saving Filtered Context Explorer Views

To preserve filter settings in the Context Explorer after you navigate away from the Context Explorer or end your session, create a browser bookmark of the Context Explorer with your preferred filters applied. Because applied filters are incorporated in the Context Explorer page URL, loading a bookmark of that page also loads the corresponding filters.

Create a browser bookmark of the Context Explorer with your preferred filters applied.

Viewing Filter Data

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 Click **Information** on any eligible filter widget.

Deleting a Filter

Step 1 Choose **Analysis** > **Context Explorer**.

Step 2 Under **Filters** at the top left, click **Clear** ( ) on any filter widget.

Tip If you want to delete all filters at once, you can click **Clear**.

CHAPTER 111

Using the Network Map

The following topics describe how to use the network map:

Requirements and Prerequisites for the Network Map

Model Support

Any.

Supported Domains

Leaf

User Roles

- Admin
- Discovery Admin

The Network Map

The Firepower System monitors traffic traveling over your network, decodes the traffic data, and then compares the data to established operating systems and fingerprints. The system then uses this data to build a detailed representation of your network, called a *network map*. In multidomain deployments, the system creates an individual network map for each leaf domain.

The system gathers data from the managed devices identified for monitoring in the network discovery policy. The managed devices detect network assets directly from monitored traffic and indirectly from processed NetFlow records. If multiple devices detect the same network asset, the system combines the information into a composite representation of the asset.

To augment data from passive detection, you can:

- Actively scan hosts using the open-source scanner, Nmap™, and add the scan results to your network map.
- Manually add host data from a third-party application using the host input feature.

The network map displays your network topology in terms of detected hosts and network devices.

You can use the network map to:

- Obtain a quick, overall view of your network.
- Select different views to suit the analysis you want to perform. Each view of the network map has the same format: a hierarchical tree with expandable categories and sub-categories. When you click a category, it expands to show you the sub-categories beneath it.
- Organize and identify subnets via the custom topology feature. For example, if each department in your organization uses a different subnet, you can assign familiar labels to those subnets using the custom topology feature.
- View detailed information by drilling down to any monitored host's *host profile*.
- Delete an asset if you are no longer interested in investigating it.

Note If the system detects activity associated with a host you deleted from a network map, it re-adds the host to the network map. Similarly, deleted applications are re-added to the network map if the system detects a change in the application (for example, if an Apache web server is upgraded to a new version). Vulnerabilities are reactivated on specific hosts if the system detects a change that makes the host vulnerable.

Tip If you want to permanently exclude a host or subnet from the network map, modify the network discovery policy. You may wish to exclude load balancers and NAT devices from monitoring if you find that they are generating excessive or irrelevant events.

Related Topics

Configuring the Network Discovery Policy, on page 2071

The Hosts Network Map

The network map on the Hosts tab displays a host count and a list of host IP addresses and primary MAC addresses. Each address or partial address is a link to the next level. This network map view provides a count of all unique hosts detected by the system, regardless of whether the hosts have one IP address or multiple IP addresses.

Use the hosts network map to view the hosts on your network, organized by subnet in a hierarchical tree, as well as to drill down to the host profiles for specific hosts.

The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

By creating a custom topology for your network, you can assign meaningful labels to your subnets, such as department names, that appear in the hosts network map. You can also view the hosts network map according to the organization you specified in the custom topology.

You can delete entire networks, subnets, or individual hosts from the hosts network map. For example, if you know that a host is no longer attached to your network, you can delete it to simplify your analysis. If the system afterwards detects activity associated with the deleted host, it re-adds the host to the network map. If you want to permanently exclude a host or subnet from the network map, modify the network discovery policy.

Caution Do not delete network devices from the network map. The system uses them to determine network topology.

On the hosts network map page, you can search only for primary MAC addresses, and the Hosts [MAC] counter includes only primary MAC addresses. For descriptions of primary and secondary MAC addresses, see Basic Host Information in the Host Profile, on page 2483.

The Network Devices Network Map

The network map on the Network Devices tab displays the network devices (bridges, routers, NAT devices, and load balancers) that connect one segment of your network to another. The map contains two sections listing devices identified by an IP address and devices identified by a MAC address.

The map also provides a count of all unique network devices detected by the system, regardless of whether the devices have one IP address or multiple IP addresses.

If you create a custom topology for your network, the labels you assign to your subnets appear in the network devices network map.

The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their types (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge
- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers

If a network device communicates using CDP, it may have one or more IP addresses. If it communicates using STP, it may only have a MAC address.

You cannot delete network devices from the network map, because the system uses their locations to determine network topology.

The host profile for a network device has a Systems section rather than an Operating Systems section, which includes a Hardware column that reflects the hardware platform for any mobile devices detected behind the network device. If a value for a hardware platform is listed under Systems, that system represents a mobile device or devices detected behind the network device. Note that mobile devices may or may not have hardware platform information, but hardware platform information is never detected for systems that are not mobile devices.

The Mobile Devices Network Map

The network map on the Mobile Devices tab displays mobile devices attached to your network. This network map also provides a count of all unique mobile devices detected by the system, regardless of whether the devices have one IP address or multiple IP addresses.

Each address or partial address is a link to the next level. You can also delete a subnet or IP address; if the system rediscovers the device, it re-adds the device to the network map.

You can also drill down to view the host profiles for the mobile devices.

To identify mobile devices, the system:

- analyzes User-Agent strings in HTTP traffic from the mobile device's mobile browser
- monitors the HTTP traffic of specific mobile applications

If you create a custom topology for your network, the labels you assign to your subnets appear in the mobile devices network map.

The Indications of Compromise Network Map

The network map on the Indications of Compromise tab displays the compromised hosts on your network, organized by IOC category. Affected hosts are listed beneath each category. Each address or partial address is a link to the next level.

From the indications of compromise network map, you can view the host profile of each host determined to have been compromised in a specific way. You can also delete (mark as resolved) any IOC category or any specific host, which removes the IOC tag from the relevant hosts. For example, you can delete an IOC category from the network map if you have determined that the issue is addressed and unlikely to recur.

Marking a host or IOC category resolved from the network map does not remove it from your network. A resolved host or IOC category reappears in the network map if your system newly detects information that triggers that IOC.

For more information about how the system determines indications of compromise, see Indications of Compromise Data, on page 2529 and subtopics.

The Application Protocols Network Map

The network map on the Application Protocols tab displays the applications running on your network, organized in a hierarchical tree by application name, vendor, version, and finally by the hosts running each application.

The applications that the system detects may change with system software and VDB updates, and if you import any add-on detectors. The release notes or advisory text for each system or VDB update contains information on any new and updated detectors. For a comprehensive up-to-date list of detectors, see the Cisco Support Site (http://www.cisco.com/cisco/web/support/index.html).

From this network map, you can view the host profile of each host that runs a specific application.

You can also delete any application category, any application running on all hosts, or any application running on a specific host. For example, you can delete an application from the network map if you know it is disabled on the host and you want to make sure the system does not use it for impact level qualification.

Deleting an application from the network map does not remove it from your network. A deleted application reappears in the network map if your system detects a change in the application (for example, if an Apache web server is upgraded to a new version) or if you restart your system's discovery function.

Depending on what you delete, the behavior differs:

- Application Category — Deleting removes the application category from the network map. All applications that reside beneath the category are removed from any host profile that contains the applications.

  For example, if you delete **http**, all applications identified as **http** are removed from all host profiles and **http** no longer appears in the applications view of the network map.

- Specific Application, Vendor, or Version — Deleting removes the affected application from the network map and from any host profiles that contain it.

  For example, if you expand the **http** category and delete **Apache**, all applications listed as Apache with any version listed beneath Apache are removed from any host profiles that contain them. Similarly, if instead of deleting **Apache**, you delete a specific version (**1.3.17**, for example), only the version you selected will be deleted from affected host profiles.

- Specific IP Address — Deleting the IP address removes it from the application list and removes the application itself from the host profile of the IP address you selected.

  For example, if you expand **http**, **Apache**, **1.3.17 (Win32)**, and then delete **172.16.1.50:80/tcp**, the Apache 1.3.17 (Win32) application is deleted from the host profile of IP address 172.16.1.50.

The Vulnerabilities Network Map

The network map on the Vulnerabilities tab displays vulnerabilities that the system has detected on your network, organized by legacy vulnerability ID (SVID), Bugtraq ID, CVE ID, or Snort ID.

From this network map, you can view the details of specific vulnerabilities, as well as the host profile of any host subject to a specific vulnerability. This information can help you evaluate the threat posed by that vulnerability to specific affected hosts.

If you determine that a specific vulnerability is not applicable to the hosts on your network (for example, you have applied a patch), you can deactivate the vulnerability. Deactivated vulnerabilities still appear on the network map, but the IP addresses of their previously affected hosts appear in gray italics. The host profiles for those hosts show deactivated vulnerabilities as invalid, though you can manually mark them as valid for individual hosts.

If there is an identity conflict for an application or operating system on a host, the system lists the vulnerabilities for both potential identities. When the identity conflict is resolved, the vulnerabilities remain associated with the current identity.

By default, the network map displays the vulnerabilities of a detected application only if the packet contains the application's vendor and version. However, you can configure the system to list the vulnerabilities for applications lacking vendor and version data by enabling the vulnerability mapping setting for the application in the Firepower Management Center configuration.

The numbers next to a vulnerability ID (or range of vulnerability IDs) represent two counts:

Affected Hosts

The first number is a count of non-unique hosts that are affected by a vulnerability or vulnerabilities. If a host is affected by more than one vulnerability, it is counted multiple times. Therefore, it is possible for the count to be higher than the number of hosts on your network. Deactivating a vulnerability

decrements this count by the number of hosts that are potentially affected by the vulnerability. If you have not deactivated any vulnerabilities for any of the potentially affected hosts for a vulnerability or range of vulnerabilities, this count is not displayed.

Potentially Affected Hosts

The second number is a count of the total number of non-unique hosts that the system has determined are *potentially* affected by a vulnerability or vulnerabilities.

Deactivating a vulnerability renders it inactive only for the hosts you designate. You can deactivate a vulnerability for all hosts that have been judged vulnerable or for a specified individual vulnerable host. After a vulnerability is deactivated, the applicable hosts' IP addresses appear in gray italics in the network map. In addition, host profiles for those hosts show deactivated vulnerabilities as invalid.

If the system subsequently detects the vulnerability on a host where it has not been deactivated (for example, on a new host in the network map), the system activates the vulnerability for that host. You have to explicitly deactivate the newly discovered vulnerability. Also, if the system detects an operating system or application change for a host, it may reactivate associated deactivated vulnerabilities.

The Host Attributes Network Map

The network map on the Host Attributes tab displays the hosts on your network organized by either user-defined or compliance white list host attributes. You cannot organize hosts using predefined host attributes in this display.

When you choose the host attribute you want to use to organize your hosts, the Firepower Management Center lists the possible values for that attribute in the network map and groups hosts based on their assigned values. For example, if you choose to organize your hosts by white list host attributes, the system displays them in categories of Compliant, Non-Compliant, and Not Evaluated.

You can also view the host profile of any host assigned a specific host attribute value.

Related Topics

Host Attributes in the Host Profile, on page 2496

Viewing Network Maps

You must be an Admin or Security Analyst user to view the network map.

Step 1 Choose **Analysis** > **Hosts** > **Network Map**.

Step 2 Click the network map you want to view.

Step 3 Continue as appropriate:

- Choose Domain — In multidomain environments, choose a leaf domain from the **Domain** drop-down list.
- Filter Hosts — If you want to filter by IP or MAC addresses, enter an address into the search field. To clear the search, click **Clear** ( ).
- Drill Down — If you want to investigate a category or host profile, drill down through the categories or subnets in the map. If you have defined a custom topology, click **(topology)** from **Hosts** to view it, then click on **(hosts)** if you want to toggle back to the default view.
- Delete — Click **Delete** ( ) next to the appropriate element to:
  - Remove an element from the map on **Hosts**, **Network Devices**, **Mobile Devices**, or **Application Protocols**.

- Mark an IOC category, compromised host, or group of compromised hosts resolved on **Indications of Compromise**.
- Deactivate a vulnerability for all hosts or a single host on **Vulnerabilities**.

- Specify Vulnerabilities Class — On **Vulnerabilities**, choose the class of vulnerabilities you want to view from the **Type** drop-down list.
- Specify Organizing Attribute — On **Host Attributes**, choose an attribute from the **Attribute** drop-down list.

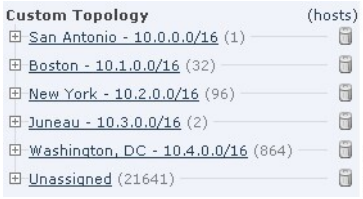
Custom Network Topologies, on page 2241
Host Profiles, on page 2482

Custom Network Topologies

Use the custom topology feature to help you organize and identify subnets in your hosts and network devices network maps.

For example, if each department within your organization uses a different subnet, you can label those subnets using the custom topology feature.

You can also view the hosts network map according to the organization you specified in the custom topology.



You can specify a custom topology's networks using any or all of the following strategies:

- You can import networks from the network discovery policy to add the networks that you configured the system to monitor.
- You can add networks to your topology manually.

The Custom Topology page lists your custom topologies and their status. If the light bulb icon next to the policy name is lit, the topology is active and affects your network map. If it is dimmed, the topology is inactive.

Related Topics

The Hosts Network Map, on page 2236

Creating Custom Topologies

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Topology** in the toolbar.

Step 3 Click **Create Topology**.

Step 4 Enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Add networks to your topology. You can use any or all of the following strategies:

- Import networks from a network discovery policy as described in Importing Networks from the Network Discovery Policy, on page 2242.
- Manually add networks as described in Manually Adding Networks to Your Custom Topology, on page 2242.

Step 7 Click **Save**.

What to do next

- Activate the topology as described in Activating and Deactivating Custom Topologies, on page 2243.

Importing Networks from the Network Discovery Policy

Step 1 Access the custom topology to which you want to import the network:

- Create a custom topology; see Creating Custom Topologies, on page 2241.
- Edit an existing custom topology; see Editing Custom Topologies, on page 2243.

Step 2 Click **Import Policy Networks**.

Step 3 Click **Load**. The system displays the topology information for the network discovery policy.

Step 4 Refine your topology:

- Rename a network in the topology by clicking **Edit** () next to the network, typing a name, and clicking **Rename**.
- Remove a network from the topology by clicking **Delete** () and then clicking **OK** to confirm.

Step 5 Click **Save**.

What to do next

- Activate the topology as described in Activating and Deactivating Custom Topologies, on page 2243.

Manually Adding Networks to Your Custom Topology

Step 1 Access the custom topology where you want to add the network:

- Create a custom topology; see Creating Custom Topologies, on page 2241.
- Edit an existing custom topology; see Editing Custom Topologies, on page 2243.

Step 2 Click **Add Network**.

Step 3 If you want to add a custom label for the network in the hosts and network devices network maps, type a **Name**.

Step 4 Enter the **IP Address** and **Netmask** (IPv4) that represent the network you want to add.

Step 5 Click **Add**.

Step 6 Click **Save**.

What to do next

- Activate the topology as described in Activating and Deactivating Custom Topologies, on page 2243.

Related Topics

Firepower System IP Address Conventions, on page 17

Activating and Deactivating Custom Topologies

Note Only one custom topology can be active at any time. If you have created multiple topologies, activating one automatically deactivates the currently active topology.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Choose **Custom Topology**.

Step 3 Click the slider next to a topology to activate or deactivate it.

Editing Custom Topologies

Changes you make to an active topology take effect immediately.

Step 1 Choose **Policies** > **Network Discovery**.

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 2 Click **Custom Topology**.

Step 3 Click **Edit** ( ) next to the topology you want to edit.

Step 4 Edit the topology as described in Creating Custom Topologies, on page 2241.

Step 5 Click **Save**.

CHAPTER 112

Incidents

The following topics describe how to configure incident handling:

About Incident Handling

Incident handling refers to the response an organization takes when a violation of its security policies is suspected. The Firepower System includes features to support you as you collect and process information that is relevant to your investigation of an incident. You can use these features to gather intrusion events and packet data that may be related to the incident. You can also use the incident as a repository for notes about any activity that you take outside of the Firepower System to mitigate the effects of the attack. For example, if your security policies require that you quarantine compromised hosts from your network, you can note that in the incident.

The Firepower System also supports an incident life cycle, allowing you to change an incident's status as you progress through your response to an attack. When you close an incident, you can note any changes you have made to your security policies as a result of any lessons learned.

Definition of an Incident

Generally, an *incident* is defined as one or more intrusion events that you suspect are involved in a possible violation of your security policies. In the Firepower System, the term also describes the feature you can use to track your response to an incident.

Some intrusion events are more important than others to the availability, confidentiality, and integrity of your network assets. For example, the port scan detection can keep you informed of port scanning activity on your network. Your security policy, however, may not specifically prohibit port scanning or see it as a high priority threat, so rather than take any direct action, you may instead want to keep logs of any port scanning for later forensic study.

On the other hand, if the system generates events that indicate hosts within your network have been compromised and are participating in distributed denial-of-service (DDoS) attacks, this activity is likely a clear violation of your security policy, and you should create an incident in the Firepower System to help you track your investigation of these events.

Common Incident Handling Processes

Preparation

You can prepare for incidents in two ways:

- by having clear and comprehensive security policies in place, as well as the hardware and software resources to enforce them
- by having a clearly defined plan to respond to incidents and a properly trained team that can implement the plan

A key part of incident handling is understanding which parts of your network are at the greatest risk. By deploying Firepower System components on those network segments, you can increase your awareness of when and how incidents occur. Also, by taking the time to carefully tune the intrusion policy for each managed device, you can ensure that the events that are generated are of the highest quality.

Detection and Notification

You cannot respond to an incident unless you can detect it. Your incident handling process should note the kinds of security-related events that you can detect and the mechanisms, both software and hardware, that you use to detect them. You should also note where you can detect violations of your security policies. If your network includes segments that are not actively or passively monitored, you need to note that as well.

The managed devices that you deploy on your network are responsible for analyzing the traffic on the segments where they are installed, for detecting intrusions, and for generating events that describe them. Keep in mind that the access control policy you deploy to each of the managed devices governs what kinds of activity they detect and how it is prioritized. You can also set notification options for certain types of intrusion events so that the incident team does not need to sift through hundreds of events. You can specify that you are notified automatically when certain high priority, high severity events are detected.

Investigation and Qualification

Your incident handling process should specify how, after a security incident is detected, an investigation is conducted. In some organizations, junior members of the team triage all the incidents and handle the less severe or lower priority cases themselves, while more senior members of the team handle high severity and high priority incidents. You should carefully outline the escalation process so that each team member understands the criteria for raising an incident's importance.

Part of the escalation process is tied to understanding how a detected event can affect the security of your network assets. For example, an attack against hosts running Microsoft SQL Server is not a high priority for organizations that use a different database server. Similarly, the attack is less important to you if you use SQL Server on your network, but you are confident that all the servers are patched and are not vulnerable to the attack. However, if someone has recently installed a copy of the vulnerable version of the software (perhaps for testing purposes), you may have a greater problem than a cursory investigation would suggest.

The Firepower System is particularly well suited to supporting the investigation and qualification process. You can create your own event classifications, and then apply them in a way that best describes the

vulnerabilities on your network. When traffic on your network triggers an event, that event is automatically prioritized and qualified for you with special indicators showing which attacks are directed against hosts that are known to be vulnerable.

The incident tracking feature in the Firepower System also includes a status indicator that you can change to show which incidents have been escalated.

Communication

All incident handling processes should specify how an incident is communicated between the incident handling team and both internal and external audiences. For example, you should consider what kinds of incidents require management intervention and at what level. Also, your process should outline how and when you communicate with outside organizations. Consider the following:

- Will some incidents require that you notify law enforcement agencies?
- If your hosts are participating in a distributed denial of service (DDoS) against a remote site, will you inform them?
- Do you want to share information with organizations such as the CERT Coordination Center (CERT/CC) or FIRST?

The Firepower System has features that you can use to gather intrusion data in standard formats such as HTML, PDF, and CSV (comma-separated values) so that you can easily share intrusion data with others.

For example, CERT/CC collects standard information about security incidents on its web site. CERT/CC looks for the kinds of information that you can easily extract from the Firepower System, such as:

- information about the affected machines, including:
  - the host name and IP
  - the time zone
  - the purpose or function of the host
- information about the sources of the attack, including:
  - the host name and IP
  - the time zone
  - whether you had any contact with an attacker
  - the estimated cost of handling the incident
- a description of the incident, including:
  - dates
  - methods of intrusion
  - the intruder tools involved
  - the software versions and patch levels
  - any intruder tool output
  - the details of vulnerabilities exploited

- the source of the attack
- any other relevant information

You can also use the comment section of an incident to record when you communicate issues and with whom.

Containment and Recovery

Your incident handling process should clearly indicate what steps are taken when a host or other network component is compromised. The range of containment and recovery options stretches from applying patches to vulnerable hosts to shutting down the target and removing it from the network. You should also consider the importance, depending upon the nature and severity of the attack, of preserving evidence in case you pursue criminal charges.

You can use the incident feature of Firepower System to maintain a record of the actions you take during the containment and recovery phase of the incident.

Lessons Learned

Each security incident, whether or not it is a successful attack, is an opportunity to review your security policies. Do you need to update your firewall rules? Do you need a more structured approach to patch management? Are unauthorized wireless access points a new security issue? Each lesson learned should feed back into your security policies and help you prepare better for the next incident.

Incident Types in the Firepower System

You can assign an incident type to each incident you create. The following types are supported by default in the Firepower System:

- Intrusion
- Denial of Service
- Unauthorized Admin Access
- Web Site Defacement
- Compromise of System Integrity
- Hoax
- Theft
- Damage
- Unknown

You can also create your own incident types.

License Requirements for Incidents

FTD License

Creating Custom Incident Types

Step 1 Choose **Analysis** > **Intrusions** > **Incidents**.

Step 2 Click **Create Incident**.

Step 3 In the **Type** area, click **Types**.

The default incident types are listed at the bottom of the page.

Step 4 In the **Incident Type Name** field, enter a name for the new incident type.

Step 5 Click **Add**.

Step 6 Click **Done**.

You can use the new incident type the next time you create or edit an incident.

Creating an Incident

In a multidomain deployment, you can view and modify incidents created in the current domain only. In an ancestor domain, you can add events to incidents from any descendant domains.

Step 1 Choose **Analysis** > **Intrusions** > **Incidents**.

Step 2 Click **Create Incident**.

Step 3 From the **Type** drop-down menu, choose the option that best describes the incident.

Step 4 In the **Time Spent** field, enter the amount of time you spent on the incident in the #d #h #m #s format, where # represents the number of days, hours, minutes, or seconds.

Step 5 In the **Summary** text box, enter a short description of the incident (up to 255 alphanumeric characters, spaces, and symbols).

Step 6 In the **Add Comment** text box, enter a more complete description for the incident (up to 8191 alphanumeric characters, spaces, and symbols).

Step 7 Add events to the incident:

- To add a selection of events, choose the events on the clipboard, and click **Add to Incident**.
- To add all events from the clipboard, click **Add All to Incident**.

Note If you want to add individual events from more than one page on the clipboard, you must add the events from one page, then add the events from the other pages separately.

Step 8 Click **Save**.

Editing an Incident

In a multidomain deployment, you can view and modify incidents created in the current domain only. In an ancestor domain, you can add events to an incident from any descendant domains.

Step 1 Choose **Analysis** > **Intrusions** > **Incidents**.

Step 2 Click **Edit** () next to the incident you want to edit.

Step 3 You can edit any of the following aspects of the incident:

- change the status
- change the type
- add events from the clipboard
- delete events

Step 4 In the **Time Spent** field, enter the amount of additional time you spent on the incident.

Step 5 In the **Add Comment** text box, indicate your changes to the incident (up to 8191 alphanumeric characters, spaces and symbols) for the incident.

Step 6 Optionally, you can add or delete events from the incident:

- To add events from the clipboard, choose the events on the clipboard and click **Add to Incident**.
- To add all the events from the clipboard, click **Add All to Incident**.
- To delete specific events from the incident, choose the events and click **Delete**.
- To delete all events from the incident, click **Delete All**.
- To update the incident without adding or deleting events, click **Save**.

Generating Incident Reports

You can use the Firepower System to generate incident reports. These reports can include the incident summary, incident status, and any comments along with information from the events you add to the incident. You can also specify whether you want to include event summary information in the report.

Step 1 Choose **Analysis** > **Intrusions** > **Incidents**.

Step 2 Click **Edit** () next to the incident you want to include in your report.

Step 3 You have two options:

- To include all the events from the incident in the report, click **Generate Report All**.
- To include specific events from the incident in the report, check the check boxes next to the events you want, and click **Generate Report**.

Step 4 Enter a name for the report.

Step 5 In **Incident Report Sections**, check the check boxes for the portions of the incident that you want to include in the report: **status**, **summary**, and **comments**.

Step 6 If you want to include event information in the report, choose the workflow you want to use and then, in **Report Sections**, specify whether you want to include event summary information.

Step 7 Check the check boxes next to the workflow pages you want to include in the report.

Step 8 Check the check boxes next to the output formats you want to use for the report: **PDF**, **HTML**, and **CSV**.

Note CSV-based incident reports include only event information. They do **not** include the status, summary, or comments from the incident.

Step 9 Click **Generate Report** and confirm that you want to update the report profile.

CHAPTER 113

Using Lookups

The following topics explain how to look up information about entities that may or may not be known to the Firepower System:

Introduction to Lookups

If your Firepower Management Center is connected to the Internet, you can use manual lookup features to find the following information:

- Regional Information Registries (RIR) information (whois) for any IP address.
- URL category and reputation as classified by the URL Filtering feature.
- Geolocation information for any IP address: country name, country code, and continent name. (To ensure that you are using up-to-date geolocation information, Cisco strongly recommends that you regularly update the Geolocation Database (GeoDB) on your Firepower Management Center.)

Related Topics

Update the Geolocation Database (GeoDB), on page 151

Performing Whois Lookups

Before you begin

- Ensure that the Firepower Management Center has Internet access; see Security, Internet Access, and Communication Ports, on page 2573.

Step 1 Choose **Analysis** > **Advanced** > **Whois**.

Step 2 Enter an IP address and click **Search**.

Related Topics

The Context Menu, on page 12

Finding URL Category and Reputation

You can manually look up category and reputation of URLs. Use this feature to see how particular URLs are evaluated in order to plan, adjust, or troubleshoot policy processing, or to investigate potentially problematic URLs that come to your attention via sources outside your Cisco solution. The categories and reputations in these results are the same as those that are used by the URL Filtering feature.

Before you begin

- The Firepower Management Center must have Internet access; see Security, Internet Access, and Communication Ports, on page 2573.
- URL Filtering and the **Query Cisco cloud for unknown URLs** option must be enabled. See Enable URL Filtering Using Category and Reputation, on page 1292 and URL Filtering Options, on page 1292.
- At least one device must be registered to the FMC and have a valid URL Filtering license assigned to it.
- You must be an Admin or Security Analyst user to perform this task.

Step 1 Select **Analysis** > **Advanced** > **URL**.

Step 2 Enter up to 250 URLs and public, routable IP addresses, in any common format (for example, URLs may be with or without "http", "www", or a subdomain, or may be shortened). Separate each entity with a space or a return.

Wildcards such as asterisks (*) are not supported.

Step 3 Click **Search**.

If you enter many URLs and your network is slow, processing may take several minutes.

If you see an error message that the URL is not valid, check your spelling or try a different variation of the URL. For example, add or omit the "www" or "http" or "https" prefix.

A URL may belong to up to six categories but has only one reputation.

Step 4 (Optional) Sort the results by clicking a column heading.

Step 5 (Optional) To save the results as a CSV file, click **Export CSV**.

An additional column for reputation level is included in the CSV file so you can sort by risk. Zero (0) represents an unknown risk, for a URL for which the system has insufficient risk data.

What to do next

If you want to view lists of possible categories and reputations, go to **Policies > Access Control > Access Control**, click a policy or add a new one, click **Add Rule**, then click **URLs**.

Finding Geolocation Information for an IP Address

You can use the geolocation lookup feature to find the country name, ISO 3166-1 three-digit country code, and continent name associated with any IP address.

Step 1 Choose **Analysis** > **Advanced** > **Geolocation**.

Step 2 To view the geolocation information for one or more IP addresses, enter the address or addresses and click **Search**. You may specify IPv4 addresses, IPv6 addresses, or both. Use a comma, semicolon, return, or any white space character to separate multiple addresses.

Tip Click **Clear** to clear the text box.

Step 3 Optionally, click the column titles to sort the data. You can sort by any field except IP Address.

Step 4 (Optional) To save the results as a CSV file, click **Export CSV**.

Related Topics

Update the Geolocation Database (GeoDB), on page 151

CHAPTER 114

Event Analysis Using External Tools

Integrate with Cisco SecureX

View and work with data from all of your Cisco security products and more through a single pane of glass, the SecureX cloud portal. Use the tools available via SecureX to enrich your threat hunts and investigations. SecureX can also provide useful appliance and device information such as whether each is running an optimal software version.

For more information about SecureX, see http://www.cisco.com/c/en/us/products/security/securex.html.

To integrate Firepower with SecureX, see the *Firepower and SecureX Integration Guide* at https://cisco.com/go/firepower-securex-documentation.

Event Analysis with Cisco SecureX threat response

Cisco SecureX threat response was formerly known as Cisco Threat Response (CTR.)

Rapidly detect, investigate, and respond to threats using Cisco SecureX threat response, the integration platform in the Cisco Cloud that lets you analyze incidents using data aggregated from multiple products, including Firepower.

- For general information about Cisco SecureX threat response, see:

  https://www.cisco.com/c/en/us/products/security/threat-response.html.

- For detailed instructions for integrating Firepower with Cisco SecureX threat response, see:

- The *Firepower and Cisco SecureX threat response Integration Guide* at https://cisco.com/go/firepower-ctr-integration-docs.

View Event Data in Cisco SecureX threat response

Before you begin

- Set up the integration as described in the *Firepower and Cisco SecureX threat response Integration Guide* at https://www.cisco.com/c/en/us/support/security/defense-center/products-installation-and-configuration-guides-list.html.
- Review the online help in Cisco SecureX threat response to learn how to find, investigate, and take action on threats.
- You will need your credentials to access Cisco SecureX threat response.

Step 1 In Firepower Management Center, do one of the following:

- To pivot to Cisco SecureX threat response from a specific event:
  a. Navigate to a page under the **Analysis** > **Intrusions** menu that lists a supported event.
  b. Right-click a source or destination IP address and select **View in Threat Response**.
- To view event info generally:
  a. Navigate to **System** > **Integrations** > **Cloud Services**.
  b. Click the link to view events in Cisco SecureX threat response.

Step 2 Sign in to Cisco SecureX threat response as prompted.

Event Investigation Using Web-Based Resources

Use the contextual cross-launch feature to quickly find more information about potential threats in web-based resources outside of the Firepower Management Center. For example, you might:

- Look up a suspicious source IP address in a Cisco or third-party cloud-hosted service that publishes information about known and suspected threats, or
- Look for past instances of a particular threat in your organization's historical logs, if your organization stores that data in a Security Information and Event Management (SIEM) application.
- Look for information about a particular file, including file trajectory information, if your organization has deployed Cisco AMP for Endpoints.

When investigating an event, you can click directly from an event in the event viewer or dashboard in the Firepower Management Center to the relevant information in the external resource. This lets you quickly gather context around a specific event based on its IP addresses, ports, protocol, domain, and/or SHA 256 hash.

For example, suppose you are looking at the Top Attackers dashboard widget and you want to find out more information about one of the source IP addresses listed. You want to see what information Talos publishes

about this IP address, so you choose the "Talos IP" resource. The Talos web site opens to a page with information about this specific IP address.

You can choose from a set of pre-defined links to commonly used Cisco and third-party threat intelligence services, and add custom links to other web-based services, and to SIEMs or other products that have a web interface. Note that some resources may require an account or a product purchase.

About Managing Contextual Cross-Launch Resources

Manage external web-based resources using the **Analysis > Advanced > Contextual Cross-Launch** page.

Pre-defined resources offered by Cisco are marked with the Cisco logo. The remaining links are third-party resources.

You can disable or delete any resources that you do not need, or you can rename them, for example by prefixing a name with a lower-case "z" so the resource sorts to the bottom of the list. Disabling a cross-launch resource disables it for all users. You cannot reinstate deleted resources, but you can re-create them.

To add a resource, see Add Contextual Cross-Launch Resources, on page 2259.

Requirements for Custom Contextual Cross-Launch Resources

When adding custom contextual cross-launch resources:

- Resources must be accessible via web browser.
- Only http and https protocols are supported.
- Only GET requests are supported; POST requests are not.
- Encoding of variables in URLs is not supported. While IPv6 addresses may require colon separators to be encoded, most services do not require this encoding.
- Up to 100 resources can be configured, including pre-defined resources.
- You must be an Admin or Security Analyst user to create a cross launch, but you can also be a read-only Security Analyst to use them.

Add Contextual Cross-Launch Resources

You can add contextual cross-launch resources such as threat intelligence services and Security Information and Event Management (SIEM) tools.

In multidomain deployments, you can see and use resources in parent domains, but you can only create and edit resources in the current domain. The total number of resources across all domains is limited to 100.

Before you begin

- See Requirements for Custom Contextual Cross-Launch Resources, on page 2259.
- If needed for the resource you will link to, create or obtain an account and the credentials needed for access. Optionally, assign and distribute credentials for each user who needs access.
- Determine the syntax of the query link for the resource that you will link to:

Access the resource via browser and, using the documentation for that resource as needed, formulate the query link needed to search for a specific sample of the type of information you want your query link to find, such as an IP address.

Run the query, then copy the resulting URL from the browser's location bar.

For example, you might have the query URL `https://www.talosintelligence.com/reputation_center/lookup?search=10.10.10.10`.

Step 1 Choose **Analysis > Advanced > Contextual Cross-Launch**.

Step 2 Click **New Cross-Launch**.

In the form that appears, all fields marked with an asterisk require a value.

Step 3 Enter a unique resource name.

Step 4 Paste the working URL string from your resource into the **URL Template** field.

Step 5 Replace the specific data (such as an IP address) in the query string with an appropriate variable: Position your cursor, then click a variable (for example, **ip**) once to insert the variable.

In the example from the "Before You Begin" section above, the resulting URL might be `https://www.talosintelligence.com/reputation_center/lookup?search={ip}`. When the contextual cross-launch link is used, the {ip} variable in the URL will be replaced by the IP address that the user right-clicks on in the event viewer or dashboard.

For a description of each variable, hover over the variable.

You can create multiple contextual cross-launch links for a single tool or service, using different variables for each.

Step 6 Click **Test with example data** ( ) to test your link with example data.

Step 7 Fix any problems.

Step 8 Click **Save**.

Investigate Events Using Contextual Cross-Launch

Before you begin

If the resource you will access requires credentials, make sure you have those credentials.

Step 1 Navigate to one of the following pages in the Firepower Management Center that shows events:

- A dashboard (**Overview > Dashboards**), or
- An event viewer page (any menu option under the **Analysis** menu that includes a table of events.)

Step 2 Right-click the event of interest and choose the contextual cross-launch resource to use.

If necessary, scroll down in the context menu to see all available options.

The data type you right-click on determines the options you see; for example, if you right-click an IP address, you will only see contextual cross-launch options that are relevant to IP addresses.

So, for example, to get threat intelligence from Cisco Talos about a source IP address in the Top Attackers dashboard widget, choose **Talos SrcIP** or **Talos IP**.

If a resource includes multiple variables, the option to choose that resource is available only for events that have a single possible value for each included variable.

The contextual cross-launch resource opens in a separate browser window.

It may take some time for the query to be processed, depending on the amount of data to be queried, speed of and demand on the resource, and so on.

Step 3 Sign in to the resource if necessary.

About Sending Syslog Messages for Security Events

You can send data related to connection, security intelligence, intrusion, and file and malware events via syslog to a Security Information and Event Management (SIEM) tool or another external event storage and management solution.

These events are also sometimes referred to as Snort® events.

About Configuring the System to Send Security Event Data to Syslog

In order to configure the system to send security event syslogs, you will need to know the following:

- Best Practices for Configuring Security Event Syslog Messaging, on page 2261
- Configuration Locations for Security Event Syslogs, on page 2266
- FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109
- If you make changes to syslog settings in any policy, you must redeploy for changes to take effect.

Best Practices for Configuring Security Event Syslog Messaging

Device and Version	Configuration Location
All	If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.

Device and Version	Configuration Location
Firepower Threat Defense version 6.3 or later	1. Configure FTD platform settings (**Devices** > **Platform Settings** > **Threat Defense Settings** > **Syslog**.) See also FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109. 2. In your access control policy Logging tab, opt to use the FTD platform settings. 3. (For intrusion events) Configure intrusion policies to use the settings in your access control policy Logging tab. (This is the default.) Overriding any of these settings is not recommended. For essential details, see Send Security Event Syslog Messages from FTD Devices, on page 2262.
All other devices	1. Create an alert response. 2. Configure access control policy Logging to use the alert response. 3. (For intrusion events) Configure syslog settings in intrusion policies. For complete details, see Send Security Event Syslog Messages from Classic Devices, on page 2264.

Send Security Event Syslog Messages from FTD Devices

This procedure documents the best practice configuration for sending syslog messages for security events (connection, Security Intelligence, intrusion, file, and malware events) from FTD devices.

Note Many FTD syslog settings are not applicable to security events. Configure only the options described in this procedure.

Before you begin

- In Firepower Management Center, configure policies to generate security events and verify that the events you expect to see appear in the applicable tables under the Analysis menu.
- Gather the syslog server IP address, port, and protocol (UDP or TCP):
- Ensure that your devices can reach the syslog server(s).
- Confirm that the syslog server(s) can accept remote messages.
- For important information about connection logging, see the chapter on Connection Logging, on page 2353.

Step 1 Configure syslog settings for your FTD device:

a) Click **Devices** > **Platform Settings**.
b) **Edit** the platform settings policy associated with your FTD device.
c) In the left navigation pane, click **Syslog**.
d) Click **Syslog Servers** and click **Add** to enter server, protocol, interface, and related information.

   If you have questions about options on this page, see Configure a Syslog Server, on page 1116.

e) Click **Syslog Settings** and configure the following settings:

   - **Enable Timestamp on Syslog Messages**
   - **Timestamp Format**
   - **Enable Syslog Device ID**

f) Click **Logging Setup**.
g) Select whether or not to **Send syslogs in EMBLEM format**.
h) **Save** your settings.

Step 2 Configure general logging settings for the access control policy (including file and malware logging):

a) Click **Policies** > **Access Control**.
b) Edit the applicable access control policy.
c) Click **Logging**.
d) Select **FTD 6.3 and later: Use the syslog settings configured in the FTD Platform Settings policy deployed on the device**.
e) (Optional) Select a **Syslog Severity**.
f) If you will send file and malware events, select **Send Syslog messages for File and Malware events**.
g) Click **Save**.

Step 3 Enable logging for Security Intelligence events for the access control policy:

a) In the same access control policy, click the **Security Intelligence** tab.
b) In each of the following locations, click **Logging** ( ) and enable beginning and end of connections and **Syslog Server**:

   - Beside **DNS Policy**.
   - In the **Block List** box, for **Networks** and for **URLs**.

c) Click **Save**.

Step 4 Enable syslog logging for each rule in the access control policy:

a) In the same access control policy, click the **Rules** tab.
b) Click a rule to edit.
c) Click the **Logging** tab in the rule.
d) Choose whether to log the beginning or end of connections, or both.

   (Connection logging generates a lot of data; logging both beginning and end generates roughly double that much data. Not every connection can be logged both at beginning and end.)

e) If you will log file events, select **Log Files**.
f) Enable **Syslog Server**.
g) Verify that the rule is "**Using default syslog configuration in Access Control Logging**."
h) Click **Add**.

i) Repeat for each rule in the policy.

Step 5 If you will send intrusion events:

a) Navigate to the intrusion policy associated with your access control policy.
b) In your intrusion policy, click **Advanced Settings > Syslog Alerting > Enabled**.
c) If necessary, click **Edit**
d) Enter options:

Option	Value
Logging Host	Unless you will send intrusion event syslog messages to a different syslog server than you will send other syslog messages, leave this blank to use the settings you have configured above.
Facility	This setting is applicable only if you specify a Logging Host on this page. For descriptions, see Syslog Alert Facilities, on page 2197.
Severity	This setting is applicable only if you specify a Logging Host on this page. For descriptions, see Syslog Severity Levels, on page 2198.

e) Click **Back**.
f) Click **Policy Information** in the left navigation pane.
g) Click **Commit Changes**.

What to do next

- (Optional) Configure different logging settings for individual policies and rules.

  See the applicable table rows in Configuration Locations for Syslogs for Connection and Security Intelligence Events (All Devices), on page 2266.

  These settings will require syslog alert responses, which are configured as described in Creating a Syslog Alert Response, on page 2196. They do not use the platform settings you configured in this procedure.

- To configure security event syslog logging for Classic devices, see Send Security Event Syslog Messages from Classic Devices, on page 2264.

- If you are done making changes, deploy your changes to managed devices.

Send Security Event Syslog Messages from Classic Devices

Before you begin

- Configure policies to generate security events.
- Ensure that your devices can reach the syslog server(s).
- Confirm that the syslog server(s) can accept remote messages.
- For important information about connection logging, see the chapter on Connection Logging, on page 2353.

Step 1 Configure an alert response for your Classic devices:

See Creating a Syslog Alert Response, on page 2196.

Step 2 Configure syslog settings in the access control policy:

a) Click **Policies** > **Access Control**.
b) Edit the applicable access control policy.
c) Click **Logging**.
d) Select **Send using specific syslog alert**.
e) Select the **Syslog Alert** you created above.
f) Click **Save**.

Step 3 If you will send file and malware events:

a) Select **Send Syslog messages for File and Malware events**.
b) Click **Save**.

Step 4 If you will send intrusion events:

a) Navigate to the intrusion policy associated with your access control policy.
b) In your intrusion policy, click **Advanced Settings** > **Syslog Alerting** > **Enabled**.
c) If necessary, click **Edit**
d) Enter options:

Option	Value
Logging Host	Unless you will send intrusion event syslog messages to a different syslog server than you will send other syslog messages, leave this blank to use the settings you have configured above.
Facility	This setting is applicable only if you specify a Logging Host on this page. See Syslog Alert Facilities, on page 2197.
Severity	This setting is applicable only if you specify a Logging Host on this page. See Syslog Severity Levels, on page 2198.

e) Click **Back**.
f) Click **Policy Information** in the left navigation pane.
g) Click **Commit Changes**.

What to do next

- (Optional) Configure different logging settings for individual access control rules. See the applicable table rows in Configuration Locations for Syslogs for Connection and Security Intelligence Events (All Devices), on page 2266. These settings will require syslog alert responses, which are configured as described in Creating a Syslog Alert Response, on page 2196. They do not use the settings you configured above.
- To configure security event syslog logging for FTD devices, see Send Security Event Syslog Messages from FTD Devices, on page 2262.

Configuration Locations for Security Event Syslogs

Configuration Locations for Syslogs for Connection and Security Intelligence Events (All Devices)

There are many places to configure logging settings. Use the table below to ensure that you set the options you need.

Important

- Pay careful attention when configuring syslog settings, especially when using inherited defaults from other configurations. Some options may NOT be available to all managed device models and software versions, as noted in the table below.
- For important information when configuring connection logging, see the chapter on Connection Logging, on page 2353.

Configuration Location	Description and More Information
Devices > **Platform Settings**, Threat Defense Settings policy, **Syslog**	This option applies only to Firepower Threat Defense devices running version 6.3 or later. Settings you configure here can be specified in the Logging settings for an Access Control policy and then used or overridden in the remaining policies and rules in this table. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109 and About Syslog, on page 1103 and subtopics.
Policies > **Access Control**, <each policy>, **Logging**	Settings you configure here are the default settings for syslogs for all connection and security intelligence events, unless you override the defaults in descendant policies and rules at the locations specified in the remaining rows of this table. Recommended setting for FTD devices running 6.3 or later: Use FTD Platform Settings. For information, see FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109 and About Syslog, on page 1103 and subtopics. Required setting for all other devices: Use a syslog alert. If you specify a syslog alert, see Creating a Syslog Alert Response, on page 2196. For more information about the settings on the Logging tab, see Logging Settings for Access Control Policies, on page 1263.

Configuration Location	Description and More Information
Policies > **Access Control**, <each policy>, **Rules**, **Default Action** row, **Logging** ()	Logging settings for the default action associated with an access control policy. See information about logging in the Access Control Rules, on page 1271 chapter and Logging Connections with a Policy Default Action, on page 2367.
Policies > **Access Control**, <each policy>, **Rules**, <each rule>, **Logging**	Logging settings for a particular rule in an access control policy. See information about logging in the Access Control Rules, on page 1271 chapter.
Policies > **Access Control**, <each policy>, **Security Intelligence**, **Logging** ()	Logging settings for Security Intelligence Block lists. Click these buttons to configure: • DNS Block List Logging Options • URL Block List Logging Options • Network Block List Logging Options (for IP addresses on the blocked list) See Configure Security Intelligence, on page 1314, including the prerequisites section, and subtopics and links.
Policies > **SSL**, <each policy>, **Default Action** row, **Logging** ()	Logging settings for the default action associated with an SSL policy. See Logging Connections with a Policy Default Action, on page 2367.
Policies > **SSL**, <each policy>, <each rule>, **Logging**	Logging settings for SSL rules. See TLS/SSL Rule Components, on page 1379.
Policies > **Prefilter**, <each policy>, **Default Action** row, **Logging** ()	Logging settings for the default action associated with a prefilter policy. See Logging Connections with a Policy Default Action, on page 2367.
Policies > **Prefilter**, <each policy>, <each prefilter rule>, **Logging**	Logging settings for each prefilter rule in a prefilter policy. See Tunnel and Prefilter Rule Components, on page 1342
Policies > **Prefilter**, <each policy>, <each tunnel rule> , **Logging**	Logging settings for each tunnel rule in a prefilter policy. See Tunnel and Prefilter Rule Components, on page 1342
Additional syslog settings for FTD cluster configurations:	The Clustering for the Firepower Threat Defense, on page 721 chapter has multiple references to syslog; search the chapter for "syslog."

Configuration Locations for Syslogs for Intrusion Events (FTD Devices Version 6.3+)

You can specify syslog settings for intrusion policies in various places and, optionally, inherit settings from the access control policy or the FTD Platform Settings or both.

Configuration Location	Description and More Information
Devices > Platform Settings, Threat Defense Settings policy, **Syslog**	Syslog destinations that you configure here can be specified in the Logging tab of an access control policy which can be the default for an intrusion policy. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109 and About Syslog, on page 1103 and subtopics.
Policies > Access Control, <each policy>, **Logging**	Default setting for syslog destination for intrusion events, if the intrusion policy does not specify other logging hosts. See Logging Settings for Access Control Policies, on page 1263.
Policies > Intrusion, <each policy>, **Advanced Settings**, enable **Syslog Alerting**, click **Edit**	To specify syslog collectors other than the destinations specified in the access control policy Logging tab, and to specify facility and severity, see Configuring Syslog Alerting for Intrusion Events, on page 2206. If you want to use the **Severity** or **Facility** or both as configured in the intrusion policy, you must also configure the logging hosts in the policy. If you use the logging hosts specified in the access control policy, the severity and facility specified in the intrusion policy will not be used.

Configuration Locations for Syslogs for Intrusion Events (Devices Other than FTD and Versions Earlier than 6.3)

- (Default) Access control policy Logging Settings for Access Control Policies, on page 1263, IF you specify a syslog alert (See Creating a Syslog Alert Response, on page 2196.)
- Or see Configuring Syslog Alerting for Intrusion Events, on page 2206.

By default, the intrusion policy uses the settings in the Logging tab of the access control policy. If settings applicable to devices other than FTD 6.3 are not configured there, syslogs will not be sent for devices other than FTD 6.3 and no warning appears.

Configuration Locations for Syslogs for File and Malware Events

Configuration Location	Description and More Information
In an access control policy: **Policies > Access Control**, <each policy>, **Logging**	This is the main location for configuring the system to send syslogs for file and malware events. If you do not use the syslog settings in FTD Platform Settings, you must also create an alert response. See Creating a Syslog Alert Response, on page 2196.

Configuration Location	Description and More Information
In Firepower Threat Defense Platform Settings: **Devices > Platform Settings**, Threat Defense Settings policy, **Syslog**	These settings apply only to Firepower Threat Defense devices running supported versions, and only if you configure the Logging tab in the access control policy to use FTD platform settings. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1109 and About Syslog, on page 1103 and subtopics.
In an access control rule: **Policies > Access Control**, <each policy>, <each rule>, **Logging**	If you do not use the syslog settings in FTD Platform Settings, you must also create an alert response. See Creating a Syslog Alert Response, on page 2196.

Anatomy of Security Event Syslog Messages

Example security event message from FTD 6.3 and later (Intrusion Event)

```
 0       1              2              3       4  5     6

<37>2018-06-27 192.168.0.81 SFIMS : %FTD-5-43000
192.168.1.10, DstIP: 192.168.1.102, SrcPort: 339
Protocol: tcp, Priority: 2, GID: 133, SID: 17, Re
Message: "DCE2_EVENT  SMB_INVALID_DSIZE", Classi
Potentially Bad Traffic, User: No Authentication
Client: NetBIOS-ssn (SMB) client, ApplicationPro
(SMB), ACPolicy: test, NAPPolicy: Balanced Secur
Connectivity, InlineResult: Blocked
```

Table 272: Components of Security Event Syslog Messages

Item Number in Sample Message	Header Element	Description
0	PRI	The priority value that represents both Facility and Severity of the alert. The value appears in the syslog messages only when you enable logging in EMBLEM format using FMC platform settings. If you enable logging of intrusion events through access control policy Logging tab, the PRI value is automatically displayed in the syslog messages. For information on how to enable the EMBLEM format, see Enable Logging and Configure Basic Settings, on page 1110. For information on PRI, see RFC5424.
1	Timestamp	Date and time the syslog message was sent from the device. • (Syslogs sent from FTD devices running version 6.3 or later) For syslogs sent using settings in the access control policy and its descendants, or if specified to use this format in the FTD Platform Settings, the date format is the format defined in the ISO 8601 timestamp format as specified in RFC 5424 (yyyy-MM-ddTHH:mm:ssZ), where the letter Z indicates the UTC time zone. • (Syslogs sent from all other devices running version 6.3 or later) For syslogs sent using settings in the access control policy and its descendants, the date format is the format defined in the ISO 8601 timestamp format as specified in RFC 5424 (yyyy-MM-ddTHH:mm:ssZ), where the letter Z indicates the UTC time zone. • Otherwise, it is the month, day, and time in UTC time zone, though the time zone is not indicated. To configure the timestamp setting in FTD Platform Settings, see Configure Syslog Settings, on page 1114.
2	Device or interface from which the message was sent. This can be: • IP address of the interface • Device hostname • Custom device identifier	(For syslogs sent from FTD devices version 6.3 and later only) If the syslog message was sent using the FTD Platform Settings, this is the value configured in **Syslog Settings** for the **Enable Syslog Device ID** option, if specified. Otherwise, this element is not present in the header. To configure this setting in FTD Platform Settings, see Configure Syslog Settings, on page 1114.

Item Number in Sample Message	Header Element	Description
3	Custom value	If the message was sent using an alert response, this is the **Tag** value configured in the alert response that sent the message, if configured. (See Creating a Syslog Alert Response, on page 2196.) Otherwise, this element is not present in the header.
4	%FTD %NGIPS	Type of device that sent the message. • %FTD is Firepower Threat Defense running version 6.3 or later • %NGIPS is all other devices running version 6.3 or later • For messages sent from devices running version 6.2.3 or earlier, this element is not present.
5	Severity	The severity specified in the syslog settings for the policy that triggered the message. For severity descriptions, see Severity Levels, on page 1104 or Syslog Severity Levels, on page 2198.
6	Event type identifier	For messages sent from devices running version 6.3 or later: • 430001: Intrusion event • 430002: Connection event logged at beginning of connection • 430003: Connection event logged at end of connection For messages sent from devices running version 6.4 or later, the following event type IDs are also used: • 430004: File event • 430005: File malware event For messages sent from devices running version 6.2.3 or earlier, an event type identifier is not present.
--	Facility	See Facility in Security Event Syslog Messages, on page 2272.

Item Number in Sample Message	Header Element	Description
--	Remainder of message	Fields and values separated by colons. Fields with empty or unknown values are omitted from messages. For field descriptions, see: • Connection and Security Intelligence Event Fields, on page 2371. • Intrusion Event Fields, on page 2402 • File and Malware Event Fields, on page 2452 **Note** Field description lists include both syslog fields and fields visible in the event viewer (menu options under the Analysis menu in the Firepower Management Center web interface.) Fields available via syslog are labeled as such. Some fields visible in the event viewer are not available via syslog. Also, some syslog fields are not included in the event viewer (but may be available via search), and some fields are combined or separated.

Facility in Security Event Syslog Messages

Facility values are not generally relevant in syslog messages for security events. However, if you require Facility, use the following table:

Device	To Include Facility in Connection Events	To Include Facility in Intrusion Events	Location in Syslog Message
FTD 6.3 and later	Use the EMBLEM option in FTD Platform Settings. Facility is always **ALERT** for connection events when sending syslog messages using FTD Platform Settings.	Use the EMBLEM option in FTD Platform Settings or configure logging using the syslog settings in the intrusion policy. If you use the intrusion policy, you must also specify the logging host in the intrusion policy settings.	Facility does not appear in the message header, but the syslog collector can derive the value based on RFC 5424, section 6.2.1.
Pre-6.3 FTD	Use an alert response.	Use the syslog setting in the intrusion policy avanced settings or an alert response identified in the access control policy Logging tab.	
Devices other than FTD	Use an alert response.	Use the syslog setting in the intrusion policy advanced settings or an alert response identified in the access control policy Logging tab.	

For more information, see Facilities and Severities for Intrusion Syslog Alerts, on page 2207 and Creating a Syslog Alert Response, on page 2196.

Firepower Syslog Message Types

Firepower can send multiple syslog data types, as described in the following table:

Syslog Data Type	See
Audit logs from FMC	Stream Audit Logs to Syslog, on page 1037 and the Auditing the System, on page 329 chapter
Audit logs from Classic devices (ASA FirePOWER, NGIPSv)	Stream Audit Logs from Classic Devices, on page 1073 and the Auditing the System, on page 329 chapter CLI command: syslog, on page 2597
Device health and network-related logs from FTD devices	About Syslog, on page 1103 and subtopics
Connection, security intelligence, and intrusion event logs from FTD devices	About Configuring the System to Send Security Event Data to Syslog, on page 2261.
Connection, security intelligence, and intrusion event logs from Classic devices	About Configuring the System to Send Security Event Data to Syslog, on page 2261
Logs for file and malware events	About Configuring the System to Send Security Event Data to Syslog, on page 2261

Limitations of Syslog for Security Events

- If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.
- It may take up to 15 minutes for events to appear on your syslog collector.
- Data for the following file and malware events is not available via syslog:
  - Retrospective events
  - Events generated by AMP for Endpoints

eStreamer Server Streaming

The Event Streamer (eStreamer) allows you to stream several kinds of event data from a Firepower Management Center to a custom-developed client application. For more information, see *Firepower System Event Streamer Integration Guide*.

Before the appliance you want to use as an eStreamer server can begin streaming eStreamer events to an external client, you must configure the eStreamer server to send events to clients, provide information about the client, and generate a set of authentication credentials to use when establishing communication. You can perform all of these tasks from the appliance's user interface. Once your settings are saved, the events you selected will be forwarded to eStreamer clients when requested.

You can control which types of events the eStreamer server is able to transmit to clients that request them.

Table 273: Event Types Transmittable by the eStreamer Server

Event Type	Description
Intrusion Events	intrusion events generated by managed devices
Intrusion Event Packet Data	packets associated with intrusion events
Intrusion Event Extra Data	additional data associated with an intrusion event such as the originating IP addresses of a client connecting to a web server through an HTTP proxy or load balancer
Discovery Events	Network discovery events
Correlation and White List Events	correlation and compliance white list events
Impact Flag Alerts	impact alerts generated by the FMC
User Events	user events
Malware Events	malware events
File Events	file events
Connection Events	information about the session traffic between your monitored hosts and all other hosts.

Comparison of Syslog and eStreamer for Security Eventing

Generally, organizations that do not currently have significant existing investment in eStreamer should use syslog rather than eStreamer to manage security event data externally.

Syslog	eStreamer
No customization required	Significant customization and ongoing maintenance required to accommodate changes in each release
Standard	Proprietary
Syslog standard does not protect against data loss, especially when using UDP	Protection against data loss
Sends directly from devices	Sends from FMC, adding processing overhead
Support for file and malware events, connection events (including security intelligence events) and intrusion events.	Support for all event types listed in eStreamer Server Streaming, on page 2274.
Some event data can be sent only from FMC. See Data Sent Only via eStreamer, Not via Syslog, on page 2275.	Includes data that cannot be sent via syslog directly from devices. See Data Sent Only via eStreamer, Not via Syslog, on page 2275.

Data Sent Only via eStreamer, Not via Syslog

The following data is available only from Firepower Management Center and thus cannot be sent via syslog from devices:

- Packet Logs
- Intrusion Event Extra Data events

  For a description, see eStreamer Server Streaming, on page 2274.
- Statistics and aggregate events
- Network Discovery events
- User activity and login events
- Correlation events
- For malware events:
  - retrospective verdicts
  - ThreatName and Disposition, unless information about the relevant SHAs has already been synchronized to the device
- The following fields:
  - Impact and ImpactFlag fields

    For a description, see eStreamer Server Streaming, on page 2274.
  - the IOC_Count field

- Most raw IDs and UUIDs.

  Exceptions:

  - Syslogs for connection events do include the following: FirewallPolicyUUID, FirewallRuleID, TunnelRuleID, MonitorRuleID, SI_CategoryID, SSL_PolicyUUID, and SSL_RuleID
  - Syslogs for intrusion events do include IntrusionPolicyUUID, GeneratorID, and SignatureID

- Extended metadata, including but not limited to:

  - User details provided by LDAP, such as full name, department, phone number, etc.

    Syslog only provides usernames in the events.

  - Details for state-based information such as SSL Certificate details.

    Syslog provides basic information like the certificate fingerprint, but will not provide other certificate details like the cert CN.

  - Detailed application information, such as App Tags and Categories.

    Syslog provides only Application names.

  Some metadata messages also include extra information about the objects.

- Geolocation information

Choosing eStreamer Event Types

The **eStreamer Event Configuration** check boxes control which events the eStreamer server can transmit. Your client must still specifically request the types of events you want it to receive in the request message it sends to the eStreamer server. For more information, see the *Firepower System Event Streamer Integration Guide*.

In a multidomain deployment, you can configure eStreamer Event Configuration at any domain level. However, if an ancestor domain has enabled a particular event type, you cannot disable that event type in the descendant domains.

You must be an Admin user to perform this task, for FMC.

Step 1 Choose **System** > **Integration**.

Step 2 Click **eStreamer**.

Step 3 Under **eStreamer Event Configuration**, check or clear the check boxes next to the types of events you want eStreamer to forward to requesting clients, described in eStreamer Server Streaming, on page 2274.

Step 4 Click **Save**.

Configuring eStreamer Client Communications

Before eStreamer can send eStreamer events to a client, you must add the client to the eStreamer server's peers database from the eStreamer page. You must also copy the authentication certificate generated by the

eStreamer server to the client. After completing these steps you do not need to restart the eStreamer service to enable the client to connect to the eStreamer server.

In a multidomain deployment, you can create an eStreamer client in any domain. The authentication certificate allows the client to request events only from the client certificate's domain and any descendant domains. The eStreamer configuration page shows only clients associated with the current domain, so if you want to download or revoke a certificate, switch to the domain where the client was created.

You must be an Admin or Discovery Admin user to perform this task, for FMC.

Step 1 Choose **System** > **Integration**.

Step 2 Click **eStreamer**.

Step 3 Click **Create Client**.

Step 4 In the **Hostname** field, enter the host name or IP address of the host running the eStreamer client.

Note If you have not configured DNS resolution, use an IP address.

Step 5 If you want to encrypt the certificate file, enter a password in the **Password** field.

Step 6 Click **Save**.
The eStreamer server now allows the host to access port 8302 on the eStreamer server and creates an authentication certificate to use during client-server authentication.

Step 7 Click **Download** ( ) next to the client hostname to download the certificate file.

Step 8 Save the certificate file to the appropriate directory used by your client for SSL authentication.

Step 9 To revoke access for a client, click **Delete** ( ) next to the host you want to remove.

Note that you do not need to restart the eStreamer service; access is revoked immediately.

Event Analysis in Splunk

You can use the Cisco Secure Firewall (f.k.a. Firepower) App for Splunk (formerly known as the Cisco Firepower App for Splunk) as an external tool to display and work with Firepower event data, to hunt and investigate threats on your network.

eStreamer is required. This is an advanced functionality. See eStreamer Server Streaming, on page 2274.

For more information, see https://cisco.com/go/firepower-for-splunk.

Event Analysis in IBM QRadar

You can use the Cisco Firepower app for IBM QRadar as an alternate way to display event data and help you analyze, hunt for, and investigate threats to your network.

eStreamer is required. This is an advanced functionality. See eStreamer Server Streaming, on page 2274.

For more information, see https://www.cisco.com/c/en/us/td/docs/security/firepower/integrations/QRadar/integration-guide-for-the-cisco-firepower-app-for-ibm-qradar.html.

History for Analyzing Event Data Using External Tools

Feature	Version	Details
Integration with IBM QRadar	6.0 and later	IBM QRadar users can use a new Firepower-specific app to analyze their event data. Available functionality is affected by your Firepower version. See Event Analysis in IBM QRadar, on page 2277.
Enhancements to integration with Cisco SecureX threat response	6.5	• Support for regional clouds: • United States (North America) • Europe • Support for additional event types: • File and malware events • High-priority connection events These are connection events related to the following: • Intrusion events • Security Intelligence events • File and malware events Modified screens: New options on **System > Integration > Cloud Services**. Supported Platforms: All devices supported in this release, either via direct integration or syslog.
Syslog	6.5	The AccessControlRuleName field is now available in intrusion event syslog messages.
Integration with Cisco Security Packet Analyzer	6.5	Support for this feature was removed.

Feature	Version	Details
Integration with Cisco SecureX threat response	6.3 (via syslog, using a proxy collector) 6.4 (direct)	Integrate Firepower intrusion event data with data from other sources for a unified view of threats on your network using the powerful analysis tools in Cisco SecureX threat response. Modified screens (version 6.4): New options on **System > Integration > Cloud Services**. Supported Platforms: Firepower Threat Defense devices running version 6.3 (via syslog) or 6.4.
Syslog support for File and Malware events	6.4	Fully-qualified file and malware event data can now be sent from managed devices via syslog. Modified screens: **Policies > Access Control > Access Control > Logging**. Supported Platforms: All managed devices running version 6.4.
Integration with Splunk	Supports all 6.x versions	Splunk users can use a new, separate Splunk app, Cisco Secure Firewall (f.k.a. Firepower) App for Splunk, to analyze events. Available functionality is affected by your Firepower version. See Event Analysis in Splunk, on page 2277.
Integration with Cisco Security Packet Analyzer	6.3	Feature introduced: Instantly query Cisco Security Packet Analyzer for packets related to an event, then click to examine the results in Cisco Security Packet Analyzer or download them for analysis in another external tool. New screens: **System** > **Integration** > **Packet Analyzer** **Analysis** > **Advanced** > **Packet Analyzer Queries** New menu options: **Query Packet Analyzer** menu item when right-clicking on an event on Dashboard pages and event tables on pages under the Analysis menu. Supported platforms: Firepower Management Center

Feature	Version	Details
Contextual cross-launch	6.3	Feature introduced: Right-click an event to look up related information in predefined or custom URL-based external resources. New screens: **Analysis** > **Advanced** > **Contextual Cross-Launch** New menu options: Multiple options when right-clicking on an event on Dashboard pages and event tables on pages under the Analysis menu. Supported platforms: Firepower Management Center
Syslog messages for connection and intrusion events	6.3	Ability to send fully-qualified connection and intrusion events to external storage and tools via syslog, using new unified and simplified configurations. Message headers are now standardized and include event type identifiers, and messages are smaller because fields with unknown and empty values are omitted. Supported Platforms: • All new functionality: FTD devices running version 6.3. • Some new functionality: Non-FTD devices running version 6.3. • Less new functionality: All devices running versions older than 6.3. For more information, see the topics under About Sending Syslog Messages for Security Events, on page 2261 and subtopics.
eStreamer	6.3	Moved eStreamer content from the Host Identity Sources chapter to this chapter and added a summary comparing eStreamer to syslog.

PART XXIV

Workflows

CHAPTER 115

Workflows

The following topics describe how to use workflows:

Overview: Workflows

A workflow is a tailored series of data pages on the Firepower Management Center web interface that analysts can use to evaluate events generated by the system.

The following types of workflows are available on the Firepower Management Center:

Predefined Workflows

Preset workflows delivered with the system. You cannot edit or delete a predefined workflow. You can, however, copy a predefined workflow and use it as the basis for a custom workflow.

Saved Custom Workflows

Custom workflows based on saved custom tables delivered with the Firepower Management Center. You can edit, delete, and copy these workflows.

Custom Workflows

Workflows that you create and customize for your specific needs, or that the system generates automatically when you create custom tables. You can edit, delete, and copy these workflows.

The data displayed in a workflow often depends on such factors as how you license and deploy your managed devices, and whether you configure features that provide the data.

Predefined Workflows

The predefined workflows described in the following sections are delivered with the system. You cannot edit or delete a predefined workflow, but you can copy a predefined workflow and use it as the basis for a custom workflow.

Predefined Intrusion Event Workflows

The following table describes the predefined intrusion event workflows included with the Firepower System.

Table 274: Predefined Intrusion Event Workflows

Workflow Name	Description
Destination Port	Because destination ports are usually tied to an application, this workflow can help you detect applications that are experiencing an uncommonly high volume of alerts. The Destination Port column can also help you identify applications that should not be present on your network.
Event-Specific	This workflow provides two useful features. Events that occur frequently may indicate: • false positives • a worm • a badly misconfigured network Events that occur infrequently are most likely evidence of a targeted attack and warrant special attention.
Events by Priority and Classification	This workflow lists events and their type in order of event priority, along with a count showing how many times each event has occurred.
Events to Destinations	This workflow provides a high-level view of which host IP addresses are being attacked and the nature of the attack; where available, you can also see information about the countries involved in attacks.
IP-Specific	This workflow shows which host IP addresses are generating the most alerts. Hosts with the greatest number of events are either public-facing and receiving worm-type traffic (indicating a good place to look for tuning) or require further investigation to determine the cause of the alerts. Hosts with the lowest counts also warrant investigation as they could be the subject of a targeted attack. Low counts may also indicate that a host may not belong on the network.
Impact and Priority	This workflow lets you find high-impact recurring events quickly. The reported impact level is shown with the number of times the event has occurred. Using this information, you can identify the high-impact events that recur most often, which might be an indicator of a widespread attack on your network.

Workflow Name	Description
Impact and Source	This workflow can help you identify the source of an attack in progress. The reported impact level is shown with the associated source IP address for the event. If, for example, events with a level 1 impact are coming from the same source IP address repeatedly, they may indicate an attacker who has identified vulnerable systems and is targeting them.
Impact to Destination	You can use this workflow to identify events repeatedly occurring on vulnerable computers, so you can address the vulnerabilities on those systems and stop any attacks in progress.
Source Port	This workflow indicates which servers are generating the most alerts. You can use this information to identify areas that require tuning, and to decide which servers require attention.
Source and Destination	This workflow identifies host IP addresses sharing high levels of alerts. Pairs at the top of the list could be false positives, and may identify areas that require tuning. You can check pairs at the bottom of the list for targeted attacks, for users accessing resources they should not be accessing, or for hosts that do not belong on the network.

Predefined Malware Workflows

The following table describes the predefined malware workflows included on the Firepower Management Center. All predefined malware workflows use the table view of malware events.

Table 275: Predefined Malware Workflows

Workflow Name	Description
Malware Summary	This workflow provides a list of the malware detected in network traffic or by AMP for Endpoints Connectors, grouped by individual threat.
Malware Event Summary	This workflow provides a quick breakdown of the different malware event types and subtypes.
Hosts Receiving Malware	This workflow provides a list of host IP addresses that have received malware, grouped by the malware files' associated dispositions.
Hosts Sending Malware	This workflow provides a list of host IP addresses that have sent malware, grouped by the malware files' associated dispositions.
Applications Introducing Malware	This workflow provides a list of host IP addresses that have received files, grouped by the associated malware dispositions for those files.

Predefined File Workflows

The following table describes the predefined file event workflows included on the Firepower Management Center. All the predefined file event workflows use the table view of file events.

Table 276: Predefined File Workflows

Workflow Name	Description
File Summary	This workflow provides a quick breakdown of the different file event categories and types, along with any associated malware dispositions.
Hosts Receiving Files	This workflow provides a list of host IP addresses that have received files, grouped by the associated malware dispositions for those files.
Hosts Sending Files	This workflow provides a list of host IP addresses that have sent files, grouped by the associated malware dispositions for those files.

Predefined Captured File Workflows

The following table describes the predefined captured file workflows included on the Firepower Management Center. All predefined captured file workflows use the table view of captured files.

Table 277: Predefined Captured File Workflows

Workflow Name	Description
Captured File Summary	This workflow provides a breakdown of captured files based on type, category, and threat score.
Dynamic Analysis Status	This workflow provides a count of captured files based on whether they have been submitted for dynamic analysis.

Predefined Connection Data Workflows

The following table describes the predefined connection data workflows included on the Firepower Management Center. All the predefined connection data workflows use the table view of connection data.

Table 278: Predefined Connection Data Workflows

Workflow Name	Description
Connection Events	This workflow provides a summary view of basic connection and detected application information, which you can then use to drill down to the table view of events.

Workflow Name	Description
Connections by Application	This workflow contains a graph of the 10 most active applications on the monitored network segment, based on the number of detected connections.
Connections by Initiator	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the number of connections where the host initiated the connection transaction.
Connections by Port	This workflow contains a graph of the 10 most active ports on the monitored network segment, based on the number of detected connections.
Connections by Responder	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the number of connections where the host IP was the responder in the connection transaction.
Connections over Time	This workflow contains a graph of the total number of connections on the monitored network segment over time.
Traffic by Application	This workflow contains a graph of the 10 most active applications on the monitored network segment, based on the number of kilobytes transmitted. Application counts reflect each detector that matched against an application connection. The same application session may be represented more than once in the list depending on whether an application protocol, web application, client detector, or internal detector matched the traffic, as well as whether the traffic originated from a mobile device or was part of an encrypted session. If the application was seen in a client flow and no specific client detector exists, a generic client may be reported. For example, you may see the same session of YouTube traffic reported as **YouTube** (because it matched a YouTube web application detector) and as **YouTube client** (because an internal YouTube detector matched against characteristics typically seen in a client session). Use the information in the connection events and network map for your network to determine more context for specific application connections.
Traffic by Initiator	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the total number of kilobytes transmitted from each address.
Traffic by Port	This workflow contains a graph of the 10 most active ports on the monitored network segment, based on the number of kilobytes transmitted.

Workflow Name	Description
Traffic by Responder	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the total number of kilobytes received by each address.
Traffic over Time	This workflow contains a graph of the total kilobytes transmitted on the monitored network segment over time.
Unique Initiators by Responder	This workflow contains a graph of the 10 most active responding host IP addresses on the monitored network segment, based on the number of unique initiators that contacted each address.
Unique Responders by Initiator	This workflow contains a graph of the 10 most active initiating host IP addresses on the monitored network segment, based on the number of unique responders that the addresses contacted.

Predefined Security Intelligence Workflows

The following table describes the predefined Security Intelligence workflows included on the Firepower Management Center. All the predefined Security Intelligence workflows use the table view of Security Intelligence events.

Table 279: Predefined Security Intelligence Workflows

Workflow Name	Description
Security Intelligence Events	This workflow provides a summary view of basic Security Intelligence and detected application information, which you can then use to drill down to the table view of events.
Security Intelligence Summary	This workflow is identical to the Security Intelligence Events workflow, but begins with the Security Intelligence Summary page, which lists security intelligence events by category and count only.
Security Intelligence with DNS Details	This workflow is identical to the Security Intelligence Events workflow, but begins with the Security Intelligence with DNS Details page, which lists Security Intelligence events by category and DNS-related characteristics.

Predefined Host Workflows

The following table describes the predefined workflows that you can use with host data.

Table 280: Predefined Host Workflows

Workflow Name	Description
Hosts	This workflow contains a table view of hosts followed by the host view. Workflow views based on the Hosts table allow you to easily view data on all IP addresses associated with a host.
Operating System Summary	You can use this workflow to analyze the operating systems in use on your network.

Predefined Indications of Compromise Workflows

The following table describes the predefined workflows that you can use with IOC (Indications of Compromise) data.

Table 281: Predefined Indications of Compromise Workflows

Workflow Name	Description
Host Indications of Compromise	This workflow begins with a summary view of IOC data grouped by count and category, and provides a detail view that further subdivides the summary data by event type. Access this workflow via the **Analysis > Hosts** menu.
Indications of Compromise by Host	You can use this workflow to gauge which hosts on your network are most likely to be compromised (based on IOC data). Access this workflow via the **Analysis > Hosts** menu.
User Indications of Compromise	This workflow begins with a summary view of IOC data grouped by count and category, and provides a detail view that further subdivides the summary data by event type. Access this workflow via the **Analysis > Users** menu.
Indications of Compromise by User	Use this workflow to gauge which users on your network are most likely to be involved in potential compromises (based on IOC data.) Access this workflow via the **Analysis > Users** menu.

Predefined Applications Workflows

The following table describes the predefined workflows that you can use with application data.

Table 282: Predefined Applications Workflows

Workflow Name	Description
Application Business Relevance	You can use this workflow to analyze running applications of each estimated business relevance level on your network, so you can monitor appropriate use of your network resources.
Application Category	You can use this workflow to analyze running applications of each category (such as email, search engine, or social networking) on your network, so you can monitor appropriate use of your network resources.
Application Risk	You can use this workflow to analyze running applications of each estimated security risk level on your network, so you can estimate the potential risk of users' activity and take appropriate action.
Application Summary	You can use this workflow to obtain detailed information about the applications and associated hosts on your network, so you can closely examine host application activity.
Applications	You can use this workflow to analyze running applications on your network, so you can gain an overview of how the network is being used.

Predefined Application Details Workflows

The following table describes the predefined workflows that you can use with application detail and client data.

Table 283: Predefined Application Details Workflows

Workflow Name	Description
Application Details	You can use this workflow to analyze the client applications on your network in more detail. The workflow then provides a table view of client applications, followed by the host view.
Clients	This workflow contains a table view of client applications, followed by the host view.

Predefined Servers Workflows

The following table describes the predefined workflows that you can use with server data.

Table 284: Predefined Servers Workflows

Workflow Name	Description
Network Applications by Count	You can use this workflow to analyze the most frequently used applications on your network.
Network Applications by Hit	You can use this workflow to analyze the most active applications on your network.
Server Details	You can use this workflow to analyze the vendors and versions of detected server application protocols in detail.
Servers	This workflow contains a table view of applications followed by the host view.

Predefined Host Attributes Workflows

The following table describes the predefined workflow that you can use with host attribute data.

Table 285: Predefined Host Attributes Workflows

Workflow Name	Description
Attributes	You can use this workflow to monitor IP addresses of hosts on your network and the hosts' status.

The Predefined Discovery Events Workflow

The following table describes the predefined workflow that you can use to view discovery and identity data.

Table 286: Predefined Discovery Event Workflows

Workflow Name	Description
Discovery Events	This workflow provides a detailed list, in table view form, of discovery events, followed by the host view.

Predefined User Workflows

The following table describes the predefined workflow that you can use to view user discovery and user identity data.

Table 287: Predefined User Workflows

Workflow Name	Description
Active Sessions	This workflow provides a list of active sessions collected by user identity sources.

Workflow Name	Description
Users	This workflow provides a list of user information collected by user identity sources.

Predefined Vulnerabilities Workflows

The following table describes the predefined vulnerabilities workflow included on the Firepower Management Center.

Table 288: Predefined Vulnerabilities Workflows

Workflow Name	Description
Vulnerabilities	You can use this workflow to review vulnerabilities in the database, including a table view of only those active vulnerabilities that apply to the detected hosts on your network.The workflow provides a vulnerability detail view, which contains a detailed description for every vulnerability that meets your constraints.

Predefined Third-Party Vulnerabilities Workflows

The following table describes the predefined third-party vulnerabilities workflows included on the Firepower Management Center.

Table 289: Predefined Third-Party Vulnerabilities Workflows

Workflow Name	Description
Vulnerabilities by IP Address	You can use this workflow to quickly see how many third-party vulnerabilities you have detected per host IP address on your monitored network.
Vulnerabilities by Source	You can use this workflow to quickly see how many third-party vulnerabilities you have detected per third-party vulnerability source, such as the QualysGuard Scanner.

Predefined Correlation and White List Workflows

There is a predefined workflow for each type of correlation data, white list events, white list violations, and remediation status events.

Table 290: Predefined Correlation Workflows

Workflow Name	Description
Correlation Events	This workflow contains a table view of correlation events.

Workflow Name	Description
White List Events	This workflow contains a table view of white list events.
Host Violation Count	This workflow provides a series of pages that list all the host IP addresses that violate at least one white list.
White List Violations	This workflow includes a table view of white list violations that lists all violations with the most recently detected violation at the top of the list. Each row in the table contains a single detected violation.
Status	This workflow contains a table view of remediation status, which includes the name of the policy that was violated and the name and status of the remediation that was applied.

Predefined System Workflows

The Firepower System is delivered with some additional workflows, including system events such as audit events and health events, as well as workflows that list results from rule update imports and active scans.

Table 291: Additional Predefined Workflows

Workflow Name	Description
Audit Log	This workflow contains a table view of the audit log that lists audit events.
Health Events	This workflow displays events triggered by the health monitoring policy.
Rule Update Import Log	This workflow contains a table view listing information about both successful and failed rule update imports.
Scan Results	This workflow contains a table view listing each completed scan.

Custom Table Workflows

You can use the custom tables feature to create tables that use the data from two or more types of events. This is useful because you can, for example, create tables and workflows that correlate intrusion event data with discovery data to allow simple searches for events that affect critical systems.

When you create a custom table, the system automatically creates a workflow that you can use to view the events associated with the table. The features in the workflow differ depending on which type of table you use. For example, custom table workflows based on the intrusion event table always end with the packet view. However, custom table workflows based on discovery events end with the host view.

Unlike workflows based on the predefined event tables, workflows based on custom tables do not have links to other types of workflows.

Using Workflows

Step 1 Choose the appropriate menu path and option as described in Workflow Selection, on page 2296.

Step 2 Navigate within the current workflow:

- To view all of the columns available in your chosen event data type, use table view pages; see Using Table View Pages, on page 2302.
- To view a subset of the columns available in your chosen event data type, use drill-down pages; see Using Drill-Down Pages, on page 2301.
- To display the corresponding row in the next page of the workflow, click **Down-Arrow** ( ).
- To move among the pages of a multipage workflow, use the tools at the bottom of each page; see Workflow Page Traversal Tools, on page 2299.
- To view the same constraints applied within a workflow for a different type of event, click **Jump to** and choose the event view from the drop-down list.

Step 3 Modify the display of the current workflow:

- Check the check boxes by one or more rows on a page to indicate which row(s) you want to affect, then click one of the buttons at the bottom of the page (for example, **View**) to perform that action for all selected rows.
- Check the check box at the top of the row to select all the rows on the page, then click one of the buttons at the bottom of the page (for example, **View**) to perform that action for all rows on the page.
- Constrain the columns in the display by clicking **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**

  Tip To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, click the expand arrow to expand the search constraints, then click the column name under Disabled Columns.

- Constrain the data view by selected values for selected fields. For information, see Event View Constraints, on page 2317 and Compound Event View Constraints, on page 2318.
- Change the time constraints on the event view. The date range located in the upper right corner of the page sets a time range for events to include in the workflow; for information, see Event Time Constraints, on page 2310.

  Note Events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.

- To sort data by columns, click the name of a column. To reverse the sort order, click the column name again. The direction indicates which column the data is sorted by, and whether the sort is **Ascending** or **Descending**.

- Click a workflow page link to display that page using any active constraints. Workflow page links appear in the upper left corner of predefined workflow table views and drill-down pages, above events and below the workflow name.

Step 4 View additional data within the current workflow:

- To view the file's trajectory map in a new window, click network file trajectory in file name and SHA-256 hash value columns. The icon is different depending on the file status; see File Trajectory Icons, on page 2299.
- To display a pop-up window of the host profile associated with an IP address, click host profile in any IP address column. The icon is different depending on the file status; see Host Profile Icons, on page 2300.
- To view the Dynamic Analysis Summary report for the highest threat score associated with a file, click threat score in any threat score column. The icon is different depending on the file's highest threat score; see Threat Score Icons, on page 2300.
- To view user profile information, click **User** or, for users associated with an indication of compromise, **Red User** in any user identity column. The user icon is dimmed if that user cannot be in the database (that is, is an AMP for Endpoints Connector user).
- To view vulnerability details for third-party vulnerabilities, click **Vulnerability** in any third-party vulnerability ID column.
- When viewing aggregated data points, hover your pointer over the flag to view the country name.
- When viewing individual data points, click flag to view further geolocation details described in Geolocation, on page 2302.

Step 5 Navigate to a different workflow:

To view the same event type using a different workflow, click **(switch workflow)** next to the workflow title, then choose the workflow you want to use. Note that you **cannot** use a different workflow for scan results.

Workflow Access by User Role

Access to a workflow is determined by the user's role. See the table below for more information.

User Role	Accessible Workflows
Administrator	Can access any workflow, and are the only users who can access the audit log, scan results, and the rule update import log.
Maintenance User	Can access health events.
Security Analyst and Security Analyst (Read Only)	Can access intrusion, malware, file, connection, discovery, vulnerability, correlation, and health workflows.

Workflow Selection

The Firepower System provides predefined workflows for the types of data listed in the following table.

Table 292: Features Using Workflows

Feature	Menu Path	Option
Intrusion events	Analysis > Intrusions	Events Reviewed Events Clipboard Incidents
Malware events	Analysis > Files	Malware Events
File events	Analysis > Files	File Events
Captured files	Analysis > Files	Captured Files
Connection events	Analysis > Connections	Events
Security Intelligence events	Analysis > Connections	Security Intelligence Events
Host events	Analysis > Hosts	Network Map Hosts Indications of Compromise Applications Application Details Servers Host Attributes Discovery Events
User events	Analysis > Users	Active Sessions User Activity Users Indications of Compromise
Vulnerability events	Analysis > Hosts	Vulnerabilities Third-Party Vulnerabilities
Correlation events	Analysis > Correlation	Correlation Events White List Events White List Violations Status

Feature	Menu Path	Option
Audit events	System > Monitoring	Audit
Health events	System > Health > Events	n/a
Rule Update Import Log	System > Updates	n/a
Scan Results	Policies > Actions > Scanners	n/a

When you view any of the kinds of data described in the above table, events appear on the first page of the default workflow for that data. You can specify a different default workflow by configuring your event view settings. Note that workflow access depends on your user role.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Related Topics

Configuring Event View Settings, on page 33

Workflow Pages

Although the data in each type of workflow is different, all workflows share a common set of features. Workflows can include several types of pages. The actions you can perform on a workflow page depend on the type of page.

Drill-down and table view pages in workflows allow you to quickly narrow your view of the data so you can zero in on events that are significant to your analysis. Table view pages and drill-down pages both support many features you can use to constrain the set of events you want to view or to navigate the workflow. When viewing data on drill-down pages or in the table view in a workflow, you can sort the data in ascending or descending order based on any available column. If the database contains more events than can be displayed on a single workflow page, you can click the links at the bottom of the page to display more events. When you click one of these links, the time window automatically pauses so that you do not see the same events twice; you can unpause the time window when you are ready.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Table Views

Table views include a column for each of the fields in the database on which your workflow is based if the page is enabled by default.

For best performance, display only the columns you need. The more columns are displayed, the more resources are required to display the data.

Note that when you disable a column on a table view, the Firepower System adds the Count column to the event view if disabling the column could create two or more identical rows.

Important To avoid a significant performance hit, do not disable any of the following columns: First Packet, Last Packet, Device, Initiator IP, Responder IP, Source Port/ICMP Type, Destination Port/ICMP Code.

These fields uniquely identify each event, and removing any of them from the view automatically adds the count field to the table, which is a resource-intensive operation, particularly when there are a large number of fields in the view.

When you click on a value in a table view page, you constrain by that value.

When you create a custom workflow, you add a table view to it by clicking **Add Table View**.

Drill-Down Pages

Generally, drill-down pages are intermediate pages that you use to narrow your investigation to a few events before moving to a table view page. Drill-down pages contain a subset of columns that are available in the database.

For example, a drill-down page for discovery events might include only the IP Address, MAC Address, and Time columns. A drill-down page for intrusion events, on the other hand, might include the Priority, Impact Flag, Inline Result, and Message columns.

Drill-down pages allow you to narrow the scope of events you are viewing and to move forward in the workflow. If you click on a value in a drill-down page, for example, you constrain by that value and move to the next page in the workflow, focusing more closely on events that match your selected values. Clicking a value in a drill-down page does not disable the column where the value is, even if the page you advance to is a table view. Note that drill-down pages for predefined workflows always have a Count column. When you create a custom workflow, you add a drill-down page to it by clicking **Add Page**.

Graphs

Workflows based on connection data can include graph pages, also called *connection graphs*.

For example, a connection graph might display a line graph that shows the number of connections detected by the system over time. Generally, connection graphs are, like drill-down pages, intermediate pages that you use to narrow your investigation.

Final Pages

The final page of a workflow depends on the type of event on which the workflow is based:

- The host view is the final page for workflows based on applications, application details, discovery events, hosts, indications of compromise (IOC), servers, white list violations, host attributes, or third-party vulnerabilities. Viewing host profiles from this page allows you to easily view data on all IP addresses associated with hosts that have multiple addresses.
- The user detail view is the final page for workflows based on users, user activity, and user indications of compromise.
- The vulnerability detail view is the final page for workflows based on Cisco vulnerabilities.
- The packet view is the final page for workflows based on intrusion events.

Workflows based on other kinds of events (for example, audit log events or malware events) do not have final pages.

On the final page of a workflow, you can expand detail sections to view specific information about each object in the set you focused on over the course of the workflow. Although the web interface does not list the constraints on the final page of a workflow, previously set constraints are retained and applied to the set of data.

Workflow Page Navigation Tools

Workflow pages provide visual cues to facilitate navigating among them and choosing what information to display during event analysis.

Workflow Page Traversal Tools

If a workflow contains multiple pages of data, the bottom of each page displays the number of pages in the workflow, as well as the tools listed in the table below which you may use to navigate among the pages:

Table 293: Workflow Page Traversal Tools

Page Traversal Tool	Action
page number (To view a different page, enter the number you wish to view, then press Enter.)	view a different page
>	view the next page
<	view the previous page
>|	jump to the last page
|<	jump to the first page

File Trajectory Icons

When a workflow page provides the opportunity to view the trajectory map for a file in a new window, a network trajectory icon appears. This icon differs depending upon the file status.

Table 294: File Trajectory Icons

File Trajectory Icon	File Status
Clean	Clean
Malware	Malware
Custom detection	Custom detection
Unknown	Unknown
Unavailable	Unavailable

Host Profile Icons

When a workflow page provides the opportunity to view the host profile associated with an IP address in a pop-up window, a host profile icon appears. If the host profile icon is dimmed, you cannot view the host profile because that host cannot be in the network map (for example, `0.0.0.0`). This icon appears different depending on the status of the host.

Table 295: Host Profile Icons

Host Profile Icon	Host Status
	Host is not tagged as potentially compromised.
	Host is tagged as potentially compromised by triggered indications of compromise (IOC) rules.
	Added to Block List (Appears only if you are performing traffic filtering based on Security Intelligence data.)
	Added to Block List, set to monitor (Appears only if you are performing traffic filtering based on Security Intelligence data.)

Threat Score Icons

When a workflow page provides the opportunity to view a Dynamic Analysis Summary report for the highest threat score associate with a file, a threat score icon appears. The icon differs depending on the file's highest threat score.

Table 296: Threat Score Icons

Threat Score Icon	Threat Score Level
Low	Low
Medium	Medium
High	High
Very High	Very high

User Icons

When a workflow page provides the opportunity to view the user identity associated with a username in a pop-up window, a user icon appears.

Table 297: User Icons

User Icon	User Status
User	User is not associated with any indications of compromise.

User Icon	User Status
Red User	User is associated with one or more indications of compromise.

The Workflow Toolbar

Each page in a workflow includes a toolbar that offers quick access to related features. The following table describes each of the links on the toolbar.

Table 298: Workflow Toolbar Links

Feature	Description
Bookmark This Page	Bookmarks the current page so you can return to it later. Bookmarking captures the constraints in effect on the page you are viewing so you can return to the same data (assuming the data still exists) at a later time.
Report Designer	Opens the report designer with the currently constrained workflow as the selection criteria.
Dashboard	Opens a dashboard relevant to your current workflow. For example, Connection Events workflows link to the Connection Summary dashboard.
View Bookmarks	Displays a list of saved bookmarks from which you can select.
Search	Displays a Search page where you can perform advanced searches on data in the workflow. You can also click the down arrow icon to select and use a saved search.

Creating Bookmarks, on page 2320
Viewing Bookmarks, on page 2320

Using Drill-Down Pages

Step 1 Access a workflow by choosing the appropriate menu path and option as described in Features Using Workflows.

Step 2 In any workflow, you have the following options:

- To drill down to the next workflow page constraining on a specific value, click a value within a row. Note that this works only on drill-down pages. Clicking a value within a row in a table view only constrains the table view and does not drill down to the next page.

- To drill down to the next workflow page constraining on some events, check the check boxes next to the events you want to view on the next workflow page, then click **View**.
- To drill down to the next workflow page keeping the current constraints, click **View All**.

Tip Table views always include “Table View” in the page name.

Using Table View Pages

Table view pages provide some features not available on drill-down, host view, packet view, or vulnerability detail pages. Use these features as described below:

Step 1 Access a workflow by choosing the appropriate menu path and option as described in Workflow Selection, on page 2296.

Step 2 Choose a table view from the workflow path displayed beneath the workflow name.

Step 3 Use the features listed below to arrange and navigate within the table view as needed:

- To display the list of disabled columns, click the Search Constraints **Expand Arrow** (▸).
- To hide the list of disabled columns, click the Search Constraints **Collapse Arrow** (▾).
- To add a disabled column back to the event view, click the Search Constraints **Expand Arrow** (▸) to expand the search constraints, then click the column name under Disabled Columns.
- To show or hide (disable) a column, click **Clear** (×) next to any column name. In the pop-up window that appears, check or clear the appropriate check boxes to indicate which columns you want to display, then click **Apply**.

Geolocation

The geolocation feature provides data about the geographical sources of routable IP addresses (country, continent, and so on). This information is available in events, asset profiles, the Context Explorer, dashboard, and other analysis tools.

Note For mobile devices and other hosts detected moving from country to country, the system may report a continent instead of a specific country.

You can use geolocation data to filter network traffic. For example, you can determine if connections are originating from or terminating in countries unconnected with your organization. In an inline deployment, you can block or rate limit those connections.

The system stores geolocation data in its geolocation database (GeoDB). Cisco issues periodic updates to the GeoDB. The About page (**Help** > **About**) shows the current GeoDB update version.

If you accept GeoDB updates, you can click the small country flag icons and ISO country codes in the Firepower Management Center web interface to obtain geolocation details about specific IP addreses; see Geolocation Detail Information, on page 2303. You can also pinpoint the detected location with third-party map tools. If you do not update the GeoDB, these details are unavailable.

You cannot view geolocation details for aggregate geolocation information, such as on the Connection Summary dashboard.

Update the Geolocation Database (GeoDB), on page 151

Geolocation Detail Information

Depending on availability, a number of fields may appear on the Geolocation Details page. The following table contains information on these fields. (Fields with no information are not displayed.)

Table 299: Geolocation Detail Fields

Field	Contents
Country	Country associated with the host's IP address, accompanied by the country's flag. The continent is listed in parentheses. Examples: `United States (North America)`, `Equatorial Guinea (Africa)`
Region	State, province, or other subregion of the country where the host is located. Examples: `VA`, `35`
City	City where the host is located. Examples: `Seattle`, `Fukuoka`
Postal Code	Postal code of the region where the host is located. Examples: `361000`, `90210`
Latitude/Longitude	Exact coordinates of the host's location. Examples: `40.0375, -76.1053`; `53.4050, -0.5484`
Maps	Links to external mapping sites (Google Maps, Yahoo Maps, Bing Maps, and OpenStreetMap). Click any link to view a contextual map of the host's approximate location.
Timezone	Time zone of the host's location, with Daylight Savings Time noted where applicable. Examples: `GMT+8:00`, `GMT-4:00 (In DST)`
ASN	Autonomous System Number (ASN) associated with the host's IP address, and any additional information about that ASN. Examples: `14618 (Amazon.com Inc.)`; `4837 (Cncgroup China169 Backbone)`

Field	Contents
ISP	Internet service provider (ISP) associated with the host's IP address. Examples: `Atlantic Broadband`; `China Unicom Ip Network`
Home/Business	Whether the host's connection is used for `Home` or `Business` purposes.
Organization	Organization associated with the host's IP address. Examples: `Amazon.com`, `Bank of America`
Domain Name	Domain name associated with the host's IP address. Examples: `amazonaws.com`, `xmcnc.net`
Connection Type	Connection type associated with the host's IP address. Examples: `Broadband`, `DSL`
Proxy Type	The type of proxy used. Examples: `Anonymous`, `Corporate`

Connection Event Graphs

In addition to workflows that use tabular drill-down pages and a final table view of events, the system can present certain connection data graphically, using data aggregated over five-minute intervals. Note that you can graph only the information used to aggregate data: source and destination IP addresses (and those hosts' associated users), destination port, transport protocol, and application protocol.

Tip You cannot graph Security Intelligence events separately from their associated connection events. For a graphical overview of Security Intelligence filtering activity, use dashboards and the Context Explorer.

There are three different types of connection graphs:

- *Pie charts* display data from one dataset grouped into discrete categories.
- *Bar graphs* display data from one or more datasets grouped into discrete categories.
- *Line graphs* plot data from one or more datasets over time, using either a standard or a velocity (rate of change) view.

Note The system displays traffic profiles as line graphs, which you can manipulate in the same way as you would any other connection graph, with some restrictions. To view traffic profiles, you must have Administrator access.

Like workflow tables, you can drill down and constrain workflow graphs to focus your analysis.

Both bar graphs and line graphs can display multiple datasets; that is, they can display several values on the y-axis for each x-axis data point. For example, you could display the total number of unique initiators and responders. Pie charts can only display one dataset.

You can display different data and datasets on a connection graph by changing either the x-axis, the y-axis, or both. On a pie chart, changing the x-axis changes the independent variable and changing the y-axis changes the dependent variable.

Related Topics

Connection Summaries (Aggregated Data for Graphs), on page 2370

Using Connection Event Graphs

On the Firepower Management Center, you can view connection event graphs and manipulate them depending on the information you are looking for.

The page you see when you access connection graphs differs depending on the workflow you use. You can use a predefined workflow, which terminates in a table view of connection events. You can also create a custom workflow that displays only the information that matches your specific needs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Connections** > **Events**.

Note If a connection event table appears instead of a graph, or to view a different graph, click **(switch workflow)** by the workflow title and choose a predefined workflow that includes graphs, or a custom workflow. Note that all predefined connection event workflows—including connection graphs—terminate in a table view of connections.

Step 2 You have the following options:

- Time Range — To adjust the time range, which is useful if the graph is blank, see Changing the Time Window, on page 2314.
- Field Names — To learn more about the data you can graph, see Connection and Security Intelligence Event Fields, on page 2371.
- Host Profile — To view the host profile for an IP address, on a graph displaying connection data by initiator or responder, click either a bar on a bar graph or a wedge on a pie chart and choose **View Host Profile**.
- User Profile — To view user profile information, on a graph displaying connection data by initiator user, click either a bar on a bar graph or a wedge on a pie chart and choose **View User Profile**.
- Other Information — To learn more information about the graphed data, position your cursor over a point on a line graph, a bar in a bar graph, or a wedge in a pie chart.
- Constrain — To constrain a connection graph by any x-axis (independent variable) criterion without advancing the workflow to the next page, click a point on a line graph, a bar on a bar graph, or a wedge on a pie chart, and choose a **View by...** option.
- Data Selection — To change the data displayed on the graph, click **X-Axis** or **Y-Axis** and choose the new data to graph. Note that changing the x-axis to or from **Time** also changes the graph type; changing the y-axis affects the displayed datasets.
- Datasets — To change the graph's dataset, click **Datasets** and choose a new dataset.
- Detach — To detach a connection graph so you can perform further analysis without affecting the default time range, click **Detach**.

Tip Click **New Window** in a detached graph to create a copy. You can then perform different analyses on each of the detached graphs. Note that traffic profiles are detached graphs.

- Drill Down — To drill down to the next page in the workflow, click a point on a line graph, a bar on a bar graph, or a wedge on a pie chart, then choose **Drill-down**. Clicking a point on a line graph changes the time range on the next page to a 10-minute span, centered on the point you clicked. Clicking a bar on a bar graph or a wedge on a pie chart constrains the next page based on the criterion represented by the bar or wedge.
- Export — To export the connection data for a graph as a CSV (comma-separated values) file, **Export Data**. Then, click **Download CSV File** and save the file.
- Graph Type: Line — To switch between a standard and velocity (rate of change) line graph, click **Velocity**, then choose **Standard** or **Velocity**.
- Graph Type: Bar and Pie — To switch between a bar graph and pie chart, click **Switch to Bar** or **Switch to Pie**. Because you cannot display multiple datasets on a pie char, if you switch to a pie chart from a bar graph that has multiple datasets, the pie chart shows only one dataset, which is selected automatically. When choosing which dataset to display, the Firepower Management Center favors total statistics over initiator and responder statistics, and favors initiator statistics over responder statistics.
- Navigate Between Pages — To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- Navigate Between Event Views — To navigate to other event views to view associated events, click **Jump to** and choose the event view from the drop-down list.
- Recenter — To recenter a line graph around a point in time without changing the length of the time range, click that point, then choose **Recenter**.
- Zoom -— To recenter a line graph around a point in time while zooming in or out, click that point, choose **Zoom**, then choose a new time span.

Note Unless you are working with a detached graph, constraining, recentering, and zooming changes the default time range for the Firepower Management Center.

Example: Constraining a Connection Graph

Example: Changing X-Axis and Y-Axis on a Pie Chart

Consider a graph of connections over time. If you constrain a point on the graph by port, a bar graph appears, showing the 10 most active ports based on the number of detected connection events, but constrained by the ten-minute time span that is centered on the point you clicked.

If you further constrain the graph by clicking on one of the bars and choosing **View by Initiator IP**, a new bar graph appears, constrained by not only the same ten-minute time span as before, but also by the port represented by the bar you clicked.

Consider a pie chart that graphs kilobytes per port. In this case, the x-axis is **Responder Port** and the y-axis is **KBytes**. This pie chart represents the total kilobytes of data transmitted over a monitored network during a certain interval. The wedges of the pie represent the percent of the data that was detected on each port.

- If you change the x-axis of the chart to **Application Protocol**, the pie chart still represents the total kilobytes of data transmitted, but the wedges of the pie represent the percentage of the data transmitted for each detected application protocol.
- If you change the y-axis of the chart to **Packets**, the pie chart represents the total number of packets transmitted over the monitored network during a certain interval, and the wedges of the pie represent the percentage of the total number of packets that was detected on each port.

Configuring Event View Settings, on page 33

Connection Graph Data Options

You can display different data on a connection graph by changing either the x-axis, the y-axis, or both. On a pie chart, changing the x-axis changes the independent variable and changing the y-axis changes the dependent variable.

Table 300: X-Axis Options

X-Axis Option	Graph Type	Graphs This Data
Application Protocol	bar or pie	by the 10 most active application protocols
Device	bar or pie	by the 10 most active managed devices
Initiator IP	bar or pie	by the 10 most active initiator host IP addresses
Initiator User	bar or pie	by the 10 most active initiator users
Responder IP	bar or pie	by the 10 most active responder host IP addresses
Responder Port	bar or pie	by the 10 most active responder ports
Source Device	bar or pie	by the 10 most active NetFlow data exporters, plus a source device named `Firepower` for all connections detected by Firepower System managed devices.
Time	line	over time Changing the y-axis to and from **Time** also changes the graph type and may change the datasets.

Table 301: Y-Axis Options

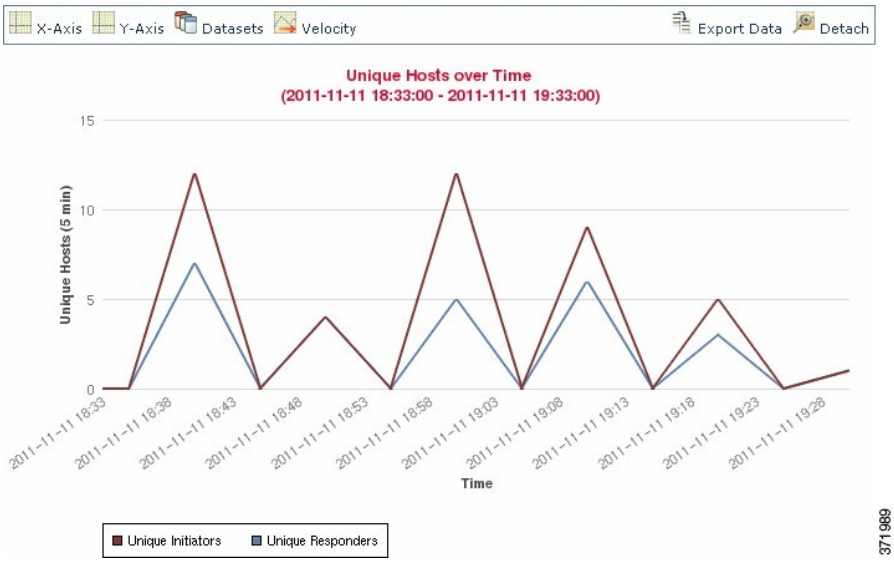
Y-Axis Option	Graphs This Data Using The X-Axis Criterion
Bytes	bytes transmitted
Connections	number of connections
KBytes	kilobytes transmitted
KBytes Per Second	kilobytes per second
Packets	number of packets transmitted
Unique Hosts	number of unique hosts detected
Unique Application Protocols	number of unique application protocols
Unique Users	number of unique users

Connection Graphs with Multiple Datasets

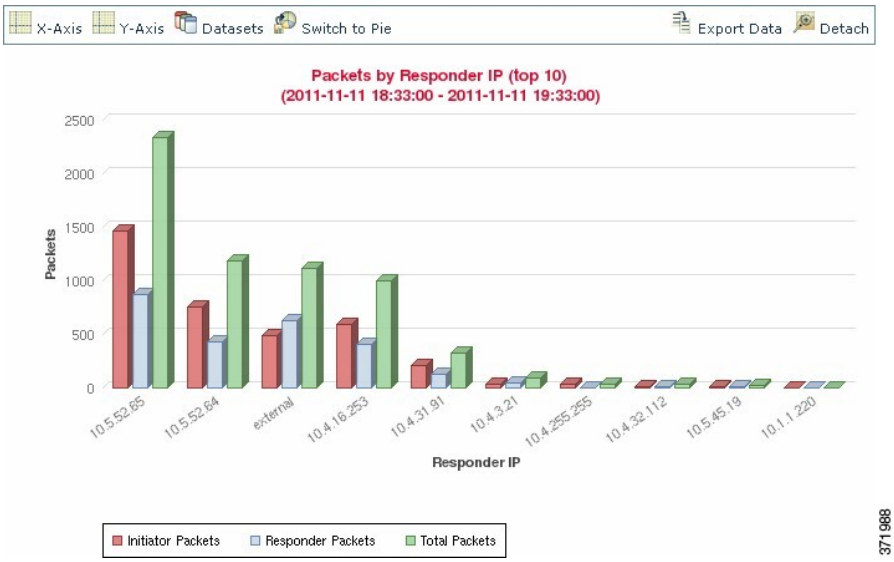
Both bar graphs and line graphs can display multiple datasets; that is, they can display several values on the y-axis for each x-axis data point. For example, you could display the total number of unique initiators and responders.

Note You **cannot** display multiple datasets on a pie chart. If you switch to a pie chart from a bar graph that has multiple datasets, the pie chart shows only one dataset, which is selected automatically. When selecting which dataset to display, the Firepower Management Center favors total statistics over initiator and responder statistics, and favors initiator statistics over responder statistics.

On line graphs, multiple datasets appear as multiple lines, each with a different color. For example, the following graphic displays the total number of unique initiators and the total number of unique responders detected on a monitored network over a one hour interval.



On bar graphs, multiple datasets appear as a set of colored bars for each x-axis data point. For example, the following bar graph displays the total packets transmitted on a monitored network, packets transmitted by initiators, and packets transmitted by responders.



Connection Graph Dataset Options

The following table describes the datasets you can display on the x-axis of a connection graph.

Table 302: Dataset Options

If the y-axis displays...	You can select as datasets...
Connections	the default only, which is the number of connections detected on the monitored network (**Connections**). This is the only option for traffic profile graphs.

If the y-axis displays...	You can select as datasets...
KBytes	combinations of: • the total kilobytes transmitted on the monitored network (**Total KBytes**) • the number of kilobytes transmitted from host IP addresses on the monitored network (**Initiator KBytes**) • the number of kilobytes received by host IP addresses on the monitored network (**Responder KBytes**)
KBytes Per Second	the default only, which is the total kilobytes per second transmitted on the monitored network (**Total KBytes Per Second**)
Packets	combinations of: • the total packets transmitted on the monitored network (**Total Packets**) • the number of packets transmitted from host IP addresses on the monitored network (**Initiator Packets**) • the number of packets received by host IP addresses on the monitored network (**Responder Packets**)
Unique Hosts	combinations of: • the number of unique session initiators on the monitored network (**Unique Initiators**) • the number of unique session responders on the monitored network (**Unique Responders**)
Unique Application Protocols	the default only, which is the number of unique application protocols on the monitored network (**Unique Application Protocols**)
Unique Users	the default only, which is the number of unique users logged into session initiators on the monitored network (**Unique Initiator Users**)

Event Time Constraints

Each event has a time stamp that indicates when the event occurred. You can constrain the information that appears in some workflows by setting the time window, sometimes called the time range.

Workflows based on events that can be constrained by time include a time range line at the top of the page.

By default, workflows use an expanding time window set to the past hour. For example, if you log in at 11:30 AM, you will see events that occurred between 10:30 AM and 11:30 AM. As time moves forward, the time window expands. At 12:30 PM, you will see events that occurred between 10:30 AM and 12:30 PM.

You can change this behavior by setting your own default time window in the event view settings. This governs three properties:

- time window type (static, expanding, or sliding)
- time window length
- the number of time windows (either multiple time windows or a single global time window)

Regardless of the default time window setting, you can manually change the time window during your event analysis by clicking the time range at the top of the page, which displays the Date/Time pop-up window. Depending on the number of time windows you configured and the type of appliance you are using, you can also use the Date/Time window to change the default time window for the type of event you are viewing.

Finally, you can pause the time window while looking at a sliding or expanding workflow. See Pause the Time Window to Temporarily Freeze the Data Set, on page 2314.

Related Topics

Configuring Event View Settings, on page 33
Using Connection and Security Intelligence Event Tables, on page 2392

Per-Session Time Window Customization for Events

Regardless of the default time window, you can manually change the time window during your event analysis.

Note Manual time window settings are valid for only the current session. When you log out and then log back in, time windows are reset to the default.

Depending on the number of time windows you configured, changing the time window for one workflow may affect other workflows on the appliance. For example, if you have a single, global time window, changing the time window for one workflow changes it for all other workflows on the appliance. On the other hand, if you are using multiple time windows, changing the audit log or health event workflow time windows has no effect on any other time window, while changing the time window for other kinds of events affects all events that can be constrained by time (with the exception of audit events and health events).

Note that because not all workflows can be constrained by time, time window settings have no effect on workflows based on hosts, host attributes, applications, application details, vulnerabilities, users, or white list violations.

Use the Time Window tab on the Date/Time window to manually configure a time window. Depending on the number of time windows you configured in your default time window settings, the tab's title is one of the following:

- **Events Time Window**, if you configured multiple time windows and are setting the time window for a workflow other than the audit log or health events workflow
- **Health Monitoring Time Window**, if you configured multiple time windows and are setting the time window for the health events workflow

- **Audit Log Time Window**, if you configured multiple time windows and are setting the time window for the audit log
- **Global Time Window**, if you configured a single time window

The first decision you must make when configuring a time window is the type of time window you want to use:

- A *static* time window displays all the events generated from a specific start time to a specific end time.
- An *expanding* time window displays all the events generated from a specific start time to the present; as time moves forward, the time window expands and new events are added to the event view.
- A *sliding* time window displays all the events generated from a specific start time (for example, one week ago) to the present; when you refresh the page, the time window "slides" so that you see only the events in the time range you configured (in this example, for the last week). To temporarily prevent the data set from updating while you are examining it, see Pause the Time Window to Temporarily Freeze the Data Set, on page 2314.

Depending on what type you select, the Date/Time window changes to give you different configuration options.

Note The Firepower System uses a 24-hour clock based on the time you specified in your time zone preferences.

Time Window Settings

The following table explains the various settings you can configure on the Time Window tab.

Table 303: Time Window Settings

Setting	Time Window Type	Description
time window type drop-down list	n/a	Select the type of time window you want to use: static, expanding, or sliding. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
Start Time calendar	static and expanding	Specify a start date and time for your time window. The maximum time range for all time windows is from midnight on January 1, 1970 (UTC) to 3:14:07 AM on January 19, 2038 (UTC). Instead of using the calendar, you can use the Presets options, described below.

Setting	Time Window Type	Description
End Time calendar	static	Specify an end date and time for your time window. The maximum time range for all time windows is from midnight on January 1, 1970 (UTC) to 3:14:07 AM on January 19, 2038 (UTC). Note that if you are using an expanding time window, the End Time calendar is grayed out and specifies that the end time is "Now." Instead of using the calendar, you can use the Presets options, described below.
Show the Last field and drop-down list	sliding	Configure the length of the sliding time window.
Presets: Last	all	Click one of the time ranges in the list to change the time window, based on the local time of the appliance. For example, clicking **1 week** changes the time window to reflect the last week. Clicking a preset changes the calendars to reflect the preset you choose.
Presets: Current	static and expanding	Click one of the time ranges in the list to change the time window, based on the local time and date of the appliance. Clicking a preset changes the calendars to reflect the preset you choose. Note that: • the current day begins at midnight • the current week begins at midnight Sunday • the current month begins at midnight on the first of the month
Presets: Synchronize with	all (not available if you are using a global time window)	Click one of: • **Events Time Window** to synchronize the current time window with the events time window • **Health Monitoring Time Window** to synchronize the current time window with the health monitoring time window • **Audit Log Time Window** to synchronize the current time window with the audit log time window

Changing the Time Window

Step 1 On a workflow constrained by time, click **Time Range** ( ) to go to the Date/Time window.

Step 2 On **Events Time Window**, set the time window as described in Time Window Settings, on page 2312.

Tip Click **Reset** to change the time window back to the default settings.

Step 3 Click **Apply**.

Pause the Time Window to Temporarily Freeze the Data Set

If you are using a sliding or expanding time window, you can pause the time window to examine a snapshot of the data provided by the workflow. This is useful because when an unpaused workflow updates, it may remove events that you want to examine or add events that you are not interested in.

The time window automatically pauses when you click a link at the bottom of the page to display another page of events; you can unpause the time window when you are ready.

When you are finished with your analysis, you can unpause the time window. Unpausing the time window updates it according to your preferences, and also updates the event view to reflect the unpaused time window.

Pausing an event time window has no effect on dashboards, nor does pausing a dashboard have any effect on pausing an event time window.

On a workflow constrained by time, choose the desired time range control:

- To pause the time window, click time range control **Pause** ( ).
- To unpause the time window, click time range control **Play** ( ).

The Default Time Window for Events

During your event analysis, you can use the Preferences tab on the Date/Time window to change the default time window for the type of event you are viewing without having to use the event view settings.

Keep in mind that changing the default time window in this way changes the default time window for only the type of event you are viewing. For example, if you configured multiple time windows, changing the default time window on the Preferences tab changes the settings for either the events, health monitoring, or audit log window, in other words, whichever time window is indicated by the first tab. If you configured a single time window, changing the default time window on the Preferences tab changes the default time window for all types of events.

Related Topics

Default Time Windows, on page 35

Default Time Window Options for Event Types

The following table explains the various settings you can configure on the Preferences tab.

Table 304: Time Window Preferences

Preference	Description
Refresh Interval	Sets the refresh interval for event views, in minutes. Entering zero disables the refresh option.
Number of Time Windows	Specify how many time windows you want to use: • Select **Multiple** to configure separate default time windows for the audit log, for health events, and for workflows based on events that can be constrained by time. • Select **Single** to use a global time window that applies to all events.
Default Time Window: Show the Last - Sliding	This setting allows you to configure a sliding default time window of the length you specify. The appliance displays all the events generated from a specific start time (for example, 1 hour ago) to the present. As you change event views, the time window "slides" so that you always see events from the last hour.
Default Time Window: Show the Last - Static/Expanding	This setting allows you to configure either a static or expanding default time window of the length you specify. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from a specific start time (for example, 1 hour ago), to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from a specific start time (for example, 1 hour ago), to the present. As you change event views, the time window expands to the present time.

Preference	Description
Default Time Window: Current Day - Static/Expanding	This setting allows you to configure either a static or expanding default time window for the current day. The current day begins at midnight, based on the time zone setting for your current session. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from midnight to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 24 hours before you log out, this time window can be more than 24 hours.
Default Time Window: Current Week - Static/Expanding	This setting allows you to configure either a static or expanding default time window for the current week. The current week begins at midnight on the previous Sunday, based on the time zone setting for your current session. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from midnight Sunday to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 1 week before you log out, this time window can be more than 1 week.

Changing the Default Time Window for Your Event Type

Step 1 On a workflow constrained by time, click **Time Range** (⏲) to go to the Date/Time window.

Step 2 Click **Preferences** and change your preferences, as described in Default Time Window Options for Event Types, on page 2314.

Step 3 Click **Save Preferences**.

Step 4 You have two options:

- To apply your new default time window settings to the event view you are using, click **Apply** to close the Date/Time window and refresh the event view.

- To continue with your analysis without applying the default time window settings, close the Date/Time window without clicking **Apply**.

Event View Constraints

The information that you see on a workflow page is determined by the constraints that you impose. For example, when you initially open an event workflow, the information is constrained to events that were generated in the previous hour.

To advance to the next page in the workflow and constrain the data you are viewing by specific values, select the rows with those values on the page and click **View**. To advance to the next page in the workflow retaining the current constraints and carrying forward all events, select **View All.**

Note If you select a row with multiple non-count values and click **View**, you create a compound constraint.

There is a third method for constraining data in a workflow. To constrain the page to the rows with values that you selected and also add the selected value to the list of constraints at the top of the page, click a value within a row on the page. For example, if you are viewing a list of logged connections and want to constrain the list to only those you allowed using access control, click **Allow** in the **Action** column. As another example, if you are viewing intrusion events and want to constrain the list to only events where the destination port is 80, click **80 (http)/tcp** in the **Destination Port/ICMP Code** column.

Tip The procedure for constraining connection events based on Monitor rule criteria is slightly different and you may need to take some extra steps. Additionally, you cannot constrain connection events by associated file or intrusion information.

You can also use searches to constrain the information in a workflow. Use this feature when you want to constrain against multiple values in a single column. For example, if you want to view the events related to two IP addresses, click **Edit Search**, then modify the appropriate IP address field on the Search page to include both addresses, and then click **Search**.

The search criteria you enter on the search page are listed as the constraints at the top of the page, with the resulting events constrained accordingly. On the Firepower Management Center, the current constraints are also applied when navigating to other workflows, unless they are compound constraints.

When searching, you must pay careful attention to whether your search constraints apply to the table you are searching. For example, client data is not available in connection summaries. If you search for connection events based on the detected client in the connection and then view the results in a connection summary event view, the Firepower Management Center displays connection data as if you had not constrained it at all. Invalid constraints are labeled as not applicable (N/A) and are marked with a strikethrough.

Constraining Events

Step 1 Access a workflow by choosing the appropriate menu path and option as described in Workflow Selection, on page 2296.

Step 2 In any workflow, you have the following options:

- To constrain the view to events that match a single value, click the desired value within a row on the page.
- To constrain the view to events that match multiple values, check the check boxes for events with those values, and click **View**.

  Note A compound constraint is added if the row contains multiple non-count values.

- To remove a constraint, click the Search Constraints **Expand Arrow** ( ) and click the name of the constraint in the expanded Search Constraints list.
- To edit constraints using the Search page, click **Edit Search.**
- To save constraints as a saved search, click **Save Search** and give the query a name.

  Note You cannot save queries containing compound constraints.

- To use the same constraints with another event view, click **Jump to** and choose the event view.

  Note You do not retain compound constraints when you switch to another workflow.

- To toggle the display of constraints click the Search Constraints **Expand Arrow** ( ) or the Search Constraints **Collapse Arrow** ( ). This is useful when the list of constraints is large and takes up most of the screen.

Compound Event View Constraints

Compound constraints are based on all non-count values for a specific event. When you select a row with multiple non-count values, you set a compound constraint that retrieves only events matching all the non-count values in that row on that page. For example, if you select a row that has a source IP address of `10.10.31.17` and a destination IP address of `10.10.31.15` and a row that has a source IP address of `172.10.10.17` and a destination IP address of `172.10.10.15`, you retrieve all of the following:

- Events that have a source IP address of 10.10.31.17 AND a destination IP address of 10.10.31.15

  OR

- Events that have a source IP address of 172.10.31.17 AND a destination IP address of 172.10.31.15

When you combine compound constraints with simple constraints, the simple constraints are distributed across each set of compound constraints. If, for example, you added a simple constraint for a protocol value of `tcp` to the compound constraints listed above, you retrieve all of the following:

- Events that have a source IP address of 10.10.31.17 AND a destination IP address of 10.10.31.15 AND a protocol of tcp

  OR

- Events that have a source IP address of 172.10.31.17 AND a destination IP address of 172.10.31.15 AND a protocol of tcp

You cannot perform a search or save a search on a compound constraint. You also cannot retain compound constraints when you use the event view links or click **(switch workflow)** to switch to another workflow. If

you bookmark an event view with compound constraints applied, the constraints are not saved with the bookmark.

Using Compound Event View Constraints

Step 1 Access a workflow by choosing the appropriate menu path and option as described in Workflow Selection, on page 2296.

Step 2 To manage compound constraints, you have the following options:

- To create a compound constraint, choose one or more rows with multiple non-count values and click **View**.
- To clear compound constraints, click the Search Constraints **Expand Arrow** ( ) and click **Compound Constraints**.

Inter-Workflow Navigation

You can navigate to other workflows using the links in the **Jump to...** drop-down list on a workflow page. Select the drop-down list to view and select additional workflows.

When you select a new workflow, properties shared by the rows you select and the constraints you set are used in the new workflow, if they are applicable. If configured constraints or event properties do not map to fields in the new workflow, they are dropped. In addition, compound constraints are not retained when you switch from one workflow to another. In addition, constraints from the captured files workflow only transfer to file and malware event workflows.

Note When you view event counts over a time range, the total number of events may not reflect the number of events for which more detailed data is available. This occurs because the system sometimes prunes older event details to manage disk space usage. To minimize the occurrence of event detail pruning, you can fine-tune event logging to log only those events most important to your deployment.

Note that unless you have either paused the time window or have configured a static time window, the time window changes when you change workflows.

This feature enhances your ability to investigate suspicious activity. For example, if you are viewing connection data and notice that an internal host is transmitting an abnormally large amount of data to an external site, you can select the responder IP address and the port as constraints and then jump to the **Applications** workflow. The applications workflow will use the responder IP address and port as IP Address and Port constraints and display additional information about the application, such as what kind of application it is. You can also click **Hosts** at the top of the page to view the host profile for the remote host.

After finding more information about the application, you can select **Correlation Events** to return to the connection data workflow, remove the Responder IP from the constraints, add the Initiator IP to constraints, and select **Application Details** to see what client the user on the initiating host used when transferring data to the remote host. Note that the Port constraint is not transferred to the Application Details page. While keeping the local host as a constraint, you can also use other navigation buttons to find additional information:

- To discover if any policies have been violated by the local host, keep the IP address as a constraint and select **Correlation Events** from the **Jump to** drop-down list.

- To find out if an intrusion rule triggered against the host, indicating a compromise, select **Intrusion Events** from the **Jump to** drop-down list.
- To view the host profile for the local host and determine if the host is susceptible to any vulnerabilities that may have been exploited, select **Hosts** from the **Jump to** drop-down list.

Bookmarks

Create a bookmark if you want to return quickly to a specific location and time in an event analysis. Bookmarks retain information about:

- the workflow you are using
- the part of the workflow you are viewing
- the page number within the workflow
- any search constraints
- any disabled columns
- the time range you are using

The bookmarks you create are available to all user accounts with bookmark access. This means that if you uncover a set of events that require more in-depth analysis, you can easily create a bookmark and turn over the investigation to another user with the appropriate privileges.

Note If the events that appear in a bookmark are deleted (either directly by a user or by automatic database cleanup), the bookmark no longer displays the original set of events.

Creating Bookmarks

In a multidomain deployment, you can only view bookmarks created in the current domain.

Step 1 During an event analysis, with the events of interest displayed, click **Bookmark This Page**.

Step 2 In the **Bookmark Name** field, enter a name.

Step 3 Click **Save Bookmark**.

Viewing Bookmarks

In a multidomain deployment, you can only view bookmarks created in the current domain.

From any event view, you have two options:

- Hover your pointer over **View Bookmarks**, and click on the desired bookmark in the drop-down menu.

- Click on click **View Bookmarks** and on the View Bookmarks page, click on the desired bookmark name or **View** () next to it.

Note If the events that originally appeared in a bookmark are deleted (either directly by a user or by automatic database cleanup), the bookmark no longer displays the original set of events.

CHAPTER 116

Searching for Events

The following topics describe how to search for events within a workflow:

Event Searches

The Firepower System generates information that is stored as events in database tables. Events contain multiple fields that describe the activity that caused the appliance to generate the event. You can create and save searches customized for your environment for any of the different event types and save them to reuse later.

When you save a search you give it a name and specify whether the search will be available to you alone or to all users of the appliance. If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search. If you previously saved a search, you can load it, make any necessary modifications, and then start the search. Custom analysis dashboard widgets, report templates, and custom roles can also use saved searches. If you have saved searches, you can delete them from the Search page.

For some event types, the Firepower System provides predefined searches that serve as examples and can provide quick access to important information about your network. You can modify fields within the predefined searches for your network environment, then save the searches to reuse later.

The search criteria you can use depends on the type of search, but the mechanics are the same. Searches return only records that match the search criteria specified for all fields.

Note Searching a custom table requires a slightly different procedure.

Related Topics

Searching Custom Tables, on page 2348

Search Constraints

Each database table has its own search page where you can enter search constraint values to apply to fields defined for the table. Depending on the type of field, special syntax may be used to specify criteria such as wildcard characters or a range of numeric values.

Search results appear on workflow pages displaying each table field in columnar layout. Some database tables can additionally be searched using fields that are not displayed as columns on workflow pages. To determine whether such a constraint applies to your search results when viewing the results on a workflow page, click

Expand Arrow ( ) to view the active search constraints.

General Search Constraints

When searching for events, observe the following general guidelines:

- All fields accept negation (`!`).
- All fields accept comma-separated lists of search values. Records that contain any of the listed values in the specified field match that search criteria.
- All fields accept comma-separated lists enclosed in quotation marks as search values.
  - For fields that may contain only a single value, records with the specified field containing the exact string specified within the quotation marks match the search criteria. For instance, a search for `A, B, "C, D, E"` will match records where the specified field contains `"A"` or `"B"` or `"C, D, E"`. This permits matching on fields that include the comma in possible values.
  - For fields that may contain multiple values at the same time, records with the specified fields containing all of the values in the quote-enclosed comma-separated list match that search criteria.
  - For fields that may contain multiple values at the same time, search criteria may include single values as well as quote-enclosed comma-separated lists. For instance, a search for `A, B, "C, D, E"` on a field that may contain one of more of these letters matches records where the specified field contains `A` or `B`, or all of `C`, `D`, and `E`.
- Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
- You can precede many numeric fields with greater than (`>`), greater than or equal to (`>=`), less than (**<**), less than or equal to (`<=`), equal to (`=`), or not equal to (`<>`) operators.

Tip When searching a field with long complicated values (such as SHA-256 hash values), you can copy the search criteria value from source material and paste it into the appropriate field on the search page.

Wildcards and Symbols in Searches

Many text fields on search pages allow you to use an asterisk (*) to match characters in a string. For example, specifying `net*` matches `network`, `netware`, `netscape`, and so on.

Note that in text fields that allow a wildcard, you **must** use the wildcard if you want to match a partial string. For example, if you are searching the audit log for all audit records that involve page views (that is, the message is Page View), searching for `Page` returns no results. Instead, specify `Page*`.

In some fields you can search for all or part of the field contents without using asterisks. In these cases, you must use quotation marks around a search string to make exact matches--otherwise, the system performs a partial match. For example, if you were to search such a field for the string `Scan Completed with Detection` without using quotation marks, the system would return records where the field contains the following strings as well as those where the field exactly matches the search string:

```
Scan Completed, No Detections
Scan completed With Detections
```

If you want to search for non-alphanumeric characters (including the asterisk character), enclose the search string in quotation marks. For example, to search for the string:

```
Find an asterisk (*)
```

enter:

```
"Find an asterisk (*)"
```

Objects and Application Filters in Searches

The Firepower System allows you to create named objects, object groups, and application filters that can be used as part of your network configuration. You can use these objects, groups, and filters as search criteria when performing or saving searches.

When you perform a search, objects, object groups, and application filters appear in the format, `${object_name}`. For example, a network object with the object name `ten_ten_network` appears as `${ten_ten_network}` in a search.

You can click **Object** (+) that appears next to a search field where you can use an object as a search criterion.

Related Topics

The Object Manager, on page 426

Time Constraints in Searches

The formats accepted by search criteria fields that take a time value are shown in the following table.

Table 305: Time Specification in Search Fields

Time Formats	Example
`today [at HH:MMam|pm]`	`today` `today at 12:45pm`
`YYYY-DDMM- HH:MM:SS`	`2006-03-22 14:22:59`

You can precede a time value with one of the following operators:

Table 306: Time Specification Operators

Operator	Example	Explanation
`<`	`< 2006-03-22 14:22:59`	Returns events with a timestamp before 2:23 PM, March 22, 2006.
`>`	`> today at 2:45pm`	Returns events with a timestamp later than today at 2:45 PM.

IP Addresses in Searches

When specifying IP addresses in searches, you can enter an individual IP address, a comma-separated list of addresses, an address block, or a range of IP addresses separated with a hyphen (-). You can also use negation.

For searches that support IPv6 (such as intrusion event, connection data, and correlation event searches) you can enter IPv4 and IPv6 addresses and CIDR/prefix length address blocks in any combination. When you search for hosts by IP address, the results include all hosts for which at least one IP address matches your search conditions, that is, a search for an IPv6 address may return hosts whose primary address in IPv4.

When you use CIDR or prefix length notation to specify a block of IP addresses, the Firepower System uses **only** the portion of the network IP address specified by the mask or prefix length. For example, if you type `10.1.2.3/8`, the Firepower System uses `10.0.0.0/8`.

Because IP addresses can be represented by network objects, you can also click the add network **Object** (+) that appears next to an IP address search field to use a network object as an IP address search criterion.

Table 307: Acceptable IP Address Syntax

To specify...	Type...	For example...
a single IP address	the IP address.	`192.168.1.1` `2001:db8::abcd`
multiple IP addresses using a list	a comma-separated list of IP addresses. Do **not** add a space before or after the commas.	`192.168.1.1,192.168.1.2` `2001:db8::b3ff,2001:db8::0202`
a range of IP addresses that can be specified with a CIDR block or prefix length	the IP address block in IPv4 CIDR or IPv6 prefix length notation.	`192.168.1.0/24` This specifies any IP in the 192.168.1.0 network with a subnet mask of 255.255.255.0, that is, 192.168.1.0 through 192.168.1.255.
a range of IP addresses that cannot be specified with a CIDR block or prefix	the IP address range using a hyphen. Do **not** add a space before or after the hyphen.	`192.168.1.1-192.168.1.5` `2001:db8::0202-2001:db8::8329`

negation of any of the other ways to specify IP addresses or ranges of IP addresses	an exclamation point in front of the IP address, block, or range.	`192.168.0.0/32,!192.168.1.10`
		`!2001:db8::/32`
		`!192.168.1.10,!2001:db8::/32`

hosts that are blocked or monitored (but would have been blocked) See Host Profile Icons, on page 2300.	In connection and Security Intelligence events, in Initiator IP and Responder IP fields: • blacklist • • monitor	--

Related Topics

Firepower System IP Address Conventions, on page 17

Managed Devices in Searches

If you group devices—whether just on the FMC, or as actual high availability or scalability configurations—searching for the name for the group correctly returns results for all devices in the group.

If the system finds a match for a group, it replaces the group name with the appropriate member device names for the purpose of performing the search. When you save a search that uses a device group in the device field the system saves the name specified in the device field and performs the device name replacement again each time the search is executed.

Ports in Searches

The Firepower System accepts specific syntax for port numbers in searches. You can enter:

- a single port number
- a comma-separated list of port numbers
- two port numbers separated by a dash to represent a range of port numbers
- a port number followed by a protocol abbreviation, separated by a forward slash (only when searching for intrusion events)
- a port number or range of port numbers preceded by an exclamation mark to indicate a negation of the specified ports

Note Do **not** use spaces when specifying port numbers or ranges.

Table 308: Port Syntax Examples

Example	Description
`21`	Returns all events on port 21, including TCP and UDP events.
`!23`	Returns all events except those on port 23.
`25/tcp`	Returns all TCP-related intrusion events on port 25.
`21/tcp,25/tcp`	Returns all TCP-related intrusion events on ports 21 and 25.
`21-25`	Returns all events on ports 21 through 25.

Event Fields in Searches

When searching for events, you can use the following fields as search criteria:

- Audit Log Workflow Fields, on page 332
- Application Data Fields, on page 2537
- Application Detail Data Fields, on page 2539

- Captured File Fields, on page 2469
- White List Event Fields, on page 2566
- Connection and Security Intelligence Event Fields, on page 2371
- Correlation Event Fields, on page 2562
- Discovery Event Fields, on page 2520
- The Health Events Table, on page 316
- Host Attribute Data Fields, on page 2528
- Host Data Fields, on page 2522
- File and Malware Event Fields, on page 2452
- Intrusion Event Fields, on page 2402
- Fields in an Intrusion Rule Update Log, on page 160
- Remediation Status Table Fields, on page 2570
- Nmap Scan Results Fields, on page 1973
- Server Data Fields, on page 2534
- Third-Party Vulnerability Data Fields, on page 2545
- User-Related Fields, on page 2547
- Vulnerability Data Fields, on page 2541
- White List Violation Fields, on page 2568

Performing a Search

You must have Admin or Security Analyst privileges to perform a search.

Step 1 Select **Analysis** > **Search**.

Tip You may also click **Search** from any page on a workflow.

Step 2 From the table drop-down list, select the type of event or data to search.

Step 3 Enter your search criteria in the appropriate fields. See the following sections for detailed information on the search criteria you can use:

- Search Constraints, on page 2323
- Audit Log Workflow Fields, on page 332
- Application Data Fields, on page 2537
- Application Detail Data Fields, on page 2539
- Captured File Fields, on page 2469

- White List Event Fields, on page 2566
- Connection and Security Intelligence Event Fields, on page 2371
- Correlation Event Fields, on page 2562
- Discovery Event Fields, on page 2520
- The Health Events Table, on page 316
- Host Attribute Data Fields, on page 2528
- Host Data Fields, on page 2522
- File and Malware Event Fields, on page 2452
- Intrusion Event Fields, on page 2402
- Fields in an Intrusion Rule Update Log, on page 160
- Remediation Status Table Fields, on page 2570
- Nmap Scan Results Fields, on page 1973
- Server Data Fields, on page 2534
- Third-Party Vulnerability Data Fields, on page 2545
- User Data Fields
- User Activity Data Fields
- Vulnerability Data Fields, on page 2541
- White List Violation Fields, on page 2568

Step 4 If you want to use the search again in the future, save the search as described in Saving a Search, on page 2329.

Step 5 Click **Search** to start the search. Your search results appear in the default workflow for the table you are searching, constrained by time (if applicable).

What to do next

- To analyze the search results using workflows, see Using Workflows, on page 2294.

Related Topics

Configuring Event View Settings, on page 33

Saving a Search

You must have Admin or Security Analyst privileges to save a search.

In a multidomain deployment, the system displays saved searches created in the current domain, which you can edit. It also displays searches saved in ancestor domains, which you cannot edit. To view and edit searches created in a lower domain, switch to that domain.

Before you begin

- Establish search criteria as described in Performing a Search, on page 2328, or load a saved search as described in Loading a Saved Search, on page 2330.

Step 1 From the Search page, if you want to save the search as private so only you can access it, check the **Private** checkbox.

Tip If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

Step 2 You have two options:

- If you want to save a new version of a loaded search, click **Save As New**.
- If you want to save a new search, or overwrite a custom search using the same name, click **Save**. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Loading a Saved Search

You must have Admin or Security Analyst privileges to load a saved search.

In a multidomain deployment, the system displays saved searches created in the current domain, which you can edit. It also displays searches saved in ancestor domains, which you cannot edit. To view and edit searches created in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Search**.

Tip You may also click **Search** from any page on a workflow.

Step 2 From the table drop-down list, choose the type of event or data to search.

Step 3 Choose the search you want to load from the **Custom Searches** list or the **Predefined Searches** list.

Step 4 If you want to use different search criteria, change the search constraints.

Step 5 If you want to use a changed search again in the future, save the search as described in Saving a Search, on page 2329.

Step 6 Click **Search**.

Query Overrides Via the Shell

System administrators can use a Linux shell-based query management tool to locate and stop long-running queries.

The query management tool allows you to locate queries running longer than a specified number of minutes and stop those queries. The tool logs an event to the audit log and to syslog when you stop a query.

Note that the `admin` internal user can access the FMC CLI. If you use an external authentication object which grants CLI access, users matching the shell access filter can also log into the CLI.

Note Leaving the search page in the web interface does not stop a query. Queries that take a long time to return results impact overall system performance while the query is running.

Shell-Based Query Management Syntax

Use the following syntax to manage long-running queries:

```
query_manager [-v] [-l [minutes]] [-k query_id [...]] [--kill-all minutes]
```

Table 309: `query_manager` Options

Option	Description
`-h, --help`	Prints a brief help message.
`-l, --list [minutes]`	Lists all queries taking longer than passed-in minutes. By default it will show all queries taking longer than 1 minute.
`-k, --kill query_id [...]`	Kills the query with the passed-in id. The option can take multiple ids.
`--kill-all minutes`	Kills all queries taking longer than passed-in minutes.
`-v, --verbose`	Verbose output including full SQL queries.

Caution For system security reasons, Cisco strongly recommends that you not establish additional Linux shell users on any appliance.

Stopping Long-Running Queries

You must be the **admin** user or externally authenticated user with CLI access

Step 1 Connect to the Firepower Management Center via `ssh`.

Step 2 Use the CLI `expert` command to access the Linux shell.

Step 3 Run `query_manager` under `sudo` using the syntax described in Shell-Based Query Management Syntax, on page 2331.

CHAPTER 117

Custom Workflows

The following topics describe how to use custom workflows:

Introduction to Custom Workflows

If the predefined and Cisco-provided custom workflows do not meet your needs, you can create and manage custom workflows.

Custom workflows are workflows that you create to meet the unique needs of your organization. When you create a custom workflow, you choose the kind of event (or database table) on which the workflow is based. On the Firepower Management Center, you can base a custom workflow on a custom table. You can also choose the pages a custom workflow contains; custom workflows can contain drill-down, table view, and host or packet view pages.

If your event evaluation process changes, you can edit custom workflows to meet your new needs. Note that you cannot edit any of the predefined workflows.

Tip You can set a custom workflow as the default workflow for any event type.

Saved Custom Workflows

In addition to predefined workflows, which cannot be modified, the Firepower Management Center includes several saved custom workflows. Each of these workflows is based on a custom table and can be modified.

In a multidomain deployment, these saved workflows belong to the Global domain and cannot be modified in lower domains.

Table 310: Saved Custom Workflows

Workflow Name	Description
Events by Impact, Priority, and Host Criticality	You can use this workflow to quickly pick out and focus in on hosts that are important to your network, currently vulnerable, and possibly currently under attack. This workflow is based on the Intrusion Events with Destination Criticality custom table.
Events by Priority and Classification	This workflow lists events and their type in order of event priority, along with a count showing how many times each event has occurred. This workflow is based on the Intrusion Events custom table.
Events with Destination, Impact, and Host Criticality	You can use this workflow to find the most recent attacks on hosts that are important to your network and currently vulnerable. This workflow is based on the Intrusion Events with Destination Criticality custom table.
Hosts with Servers Default Workflow	You can use this workflow to quickly view the basic information in the Hosts with Servers custom table. This workflow is based on the Hosts with Servers custom table.
Intrusion Events with Destination Criticality Default Workflow	You can use this workflow to quickly view the basic information in the Intrusion Events with Destination Criticality custom table. This workflow is based on the Intrusion Events with Destination Criticality custom table.
Intrusion Events with Source Criticality Default Workflow	You can use this workflow to quickly view the basic information in the Intrusion Events with Source Criticality custom table. This workflow is based on the Intrusion Events with Source Criticality custom table.
Server and Host Details	You can use this workflow to determine what servers are most frequently used on your network and which hosts are running those servers. This workflow is based on the Hosts with Servers custom table.

Custom Workflow Creation

If the predefined and Cisco-provided custom workflows do not meet your needs, you can create custom workflows.

Tip Instead of creating a new custom workflow, you can export a custom workflow from another appliance and then import it onto your appliance. You can then edit the imported workflow to suit your needs.

When you create a custom workflow, you:

- Select a table to be the source of the workflow
- Provide a workflow name
- Add drill-down pages and table view pages to the workflow

For each drill-down page in the workflow, you can:

- Provide a name that appears at the top of the page in the web interface
- Include up to five columns per page
- Specify a default sort order, ascending or descending

You can add table view pages in any position in the sequence of workflow pages. They do not have any editable properties, such as a page name, sort order, or user-definable column positions.

Note You must add at least one drill-down page or a table view of events to a custom workflow.

Note If you selected **Vulnerabilities** as the table type, then add **IP Address** as a table column, the IP Address column does not appear when you are viewing vulnerabilities using your custom workflow, unless you use the search feature to constrain the workflow to view a specific IP address or block of addresses.

The final page of a custom workflow depends on the table on which you base the workflow, as described in the following table. These final pages are added by default when you create the workflow.

Table 311: Custom Workflow Final Pages

Event/Asset Type	Final Page
Discovery events	Hosts
Vulnerabilities	Vulnerability detail
Third-party vulnerabilities	Hosts
Users	Users
Indications of compromise	Hosts or users
Intrusion events	Packets

The system does not add a final page to custom workflows based on other kinds of events (for example, audit log or malware events).

Custom workflows based on connection data are like other custom workflows, except you can include drill-down pages containing connection summary data, and connection data graph pages as well as drill-down pages containing data for individual connections and table view pages.

Creating Custom Workflows Based on Non-Connection Data

You must have Admin or Security Analyst privileges to create a custom workflow based on non-connetion data.

Step 1 Choose **Analysis** > **Advanced** > **Custom Workflows**.

Step 2 Click **Create Custom Workflow**.

Step 3 Enter a name for the workflow in the **Name** field.

Step 4 Optionally, enter a **Description**.

Step 5 Choose the table you want to include from the **Table** drop-down list.

Step 6 If you want to add one or more drill-down pages to the workflow, click **Add Page**.

Step 7 Enter a name for the page in the **Page Name** field.

Step 8 Under Column 1, choose a sort priority and a table column. This column will appear in the leftmost column of the page.

Example:

For example, to create a page showing the destination ports that are targeted, and to sort the page by count, choose **2** from the **Sort Priority** drop-down list and **Destination Port/ICMP Code** from the **Field** drop-down list.

Step 9 Continue choosing fields to include and setting their sort priority until you have specified all the fields you want to appear on the page.

Step 10 If you want to add a table view page to the workflow, click **Add Table View**.

Step 11 Click **Save**.

Creating Custom Connection Data Workflows

Custom workflows based on connection data are like other custom workflows, except you can include connection data graph pages as well as drill-down pages and table view pages. You can include as many of each type of page in the workflow as you want, in any order. Each connection data graph page contains a single graph, which can be a line graph, bar graph, or pie chart. On line and bar graphs, you may include more than one dataset.

You must have Admin privileges to create a custom workflow based on connection data.

Step 1 Choose **Analysis** > **Advanced** > **Custom Workflows**.

Step 2 Click **Create Custom Workflow**.

Step 3 Enter a name for the workflow in the **Name** field.

Step 4 Optionally, enter a **Description**.

Step 5 From the **Table** drop-down list, choose **Connection Events**.

Step 6 If you want to add one or more drill-down pages to the workflow, you have two options:

- Click **Add Page** to add a drill-down page that contains data on individual connections,
- Click **Add Summary Page** to add a drill-down page that contains connection summary data.

Step 7 Enter a name for the page in the **Page Name** field.

Step 8 Under **Column 1**, choose a sort priority and a table column. This column will appear in the leftmost column of the page.

Step 9 Continue choosing fields to include and setting their sort priority until you have specified all the fields you want to appear on the page.

Example:

For example, to create a page showing the amount of traffic transmitted over your monitored network and to sort the page by the responders that transmitted the most traffic, choose **1** from the **Sort Priority** drop-down list and **Responder Bytes** from the **Field** drop-down list.

Step 10 If you want to add one or more graph pages to the workflow, click **Add Graph**.

Step 11 Enter a name for the page in the **Graph Name** field.

Step 12 Choose the type of graph you want to include on the page:

- line graph (**Line chart** ())
- bar graph(**Bar chart** ())
- pie chart (**Pie chart** ())

Step 13 Specify what kind of data you want to graph by choosing the x- and y-axes of the graph.

On a pie chart, the x-axis represents the independent variable and the y-axis represents the dependent variable.

Step 14 Choose the datasets you want to include on the graph.

Note that pie charts can include only one data set.

Step 15 If you want to add a table view of connection data, click **Add Table View**.

Table views are not configurable.

Step 16 Click **Save**.

Custom Workflow Use and Management

The method you use to view a workflow depends on whether the workflow is based on one of the predefined event tables or on a custom table.

If your custom workflow is based on a predefined event table, access it in the same way that you would access a workflow that ships with the appliance. For example, to access a custom workflow based on the Hosts table, choose **Analysis** > **Hosts** > **Hosts**. If, on the other hand, your custom workflow is based on a custom table, you must access it from the Custom Tables page.

If your event evaluation process changes, you can edit custom workflows to meet your new needs. Note that you cannot edit any of the predefined workflows.

Tip You can set a custom workflow as the default workflow for any event type.

Viewing Custom Workflows Based on Predefined Tables

You must have Admin, Maintenance, or Security Analyst privileges to view a custom workflow.

Step 1 Choose the appropriate menu path and option for the table on which you based your custom workflow, as described in the Workflow Selection, on page 2296.

Step 2 To use a different workflow, including a custom workflow, click **(switch workflow)** next to the current workflow title.

Step 3 If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Event Time Constraints, on page 2310.

Viewing Custom Workflows Based on Custom Tables

You must have Admin or Security Analyst privileges to view a custom workflow that is based on custom tables.

In a multidomain deployment, the system displays custom workflows created in the current domain, which you can edit. It also displays custom workflows created in ancestor domains, which you cannot edit. To view and edit custom workflows in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **View** ( ) next to the custom table you want to view, or click the name of the custom table.

Step 3 To use a different workflow, including a custom workflow, click **(switch workflow)** beside the current workflow title.

Step 4 If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Event Time Constraints, on page 2310.

Editing Custom Workflows

You must have Admin or Security Analyst privileges to edit a custom workflow.

In a multidomain deployment, the system displays custom workflows created in the current domain, which you can edit. It also displays custom workflows created in ancestor domains, which you cannot edit. To view and edit custom workflows in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Workflows**.

Step 2 Click **Edit** ( ) next to the name of the workflow that you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Make any changes that you want to the workflow.

Step 4 Click **Save**.

CHAPTER 118

Custom Tables

The following topics describe how to use custom tables:

Introduction to Custom Tables

As the Firepower System collects information about your network, the Firepower Management Center stores it in a series of database tables. When you use a workflow to view the resulting information, the Firepower Management Center pulls the data from one of these tables. For example, the columns on each page of the Network Applications by Count workflow are taken from the fields in the Applications table.

If you determine that your analysis of the activity on your network would be enhanced by combining fields from different tables, you can create a custom table. For example, you could combine the host criticality information from the predefined Host Attributes table with the fields from the predefined Connection Data table and then examine connection data in a new context.

Note that you can create custom workflows for either predefined or custom tables.

Predefined Custom Tables

Custom tables contain fields from two or more predefined tables. The Firepower System is delivered with a number of system-defined custom tables, but you can create additional custom tables that contain only information that matches your specific needs.

For example, the Firepower System is delivered with system-defined custom tables that correlate intrusion event data with host data, so you can search for events that impact critical systems and view the results of that search in one workflow.

In a multidomain deployment, the predefined custom tables belong to the Global domain and cannot be modified in lower domains.

The following table describes the custom tables provided with the system.

Table 312: System-Defined Custom Tables

Table	Description
Hosts with Servers	Includes fields from the Hosts and Servers tables, providing you with information about the detected applications running on your network, as well as basic operating system information about the hosts running those applications.
Intrusion Events with Destination Criticality	Includes fields from the Intrusion Events table and the Hosts table, providing you with information on the intrusion events, as well as the host criticality of the destination host involved in each intrusion event. You can use this table to search for intrusion events involving destination hosts with high host criticality.
Intrusion Events with Source Criticality	Includes fields from the Intrusion Events table and the Hosts table, providing you with information on the intrusion events and the host criticality of the source host involved in each intrusion event. You can use this table to search for intrusion events involving source hosts with high host criticality.

Possible Table Combinations

When you create a custom table, you can combine fields from predefined tables that have related data. The following table lists the predefined tables you can combine to create a new custom table. Keep in mind that you can create a custom table that combines fields from more than two predefined custom tables.

Table 313: Custom Table Combinations

You can combine fields from...	With fields from...
Applications	• Correlation Events • Intrusion Events • Connection Summary Data • Host Attributes • Application Details • Discovery Events • Connection Events • Hosts • Servers • White List Events

You can combine fields from...	With fields from...
Correlation Events	• Applications • Host Attributes • Hosts
Intrusion Events	• Applications • Host Attributes • Hosts • Servers
Connection Summary Data	• Applications • Host Attributes • Hosts • Servers
Host Indications of Compromise	• Applications • Application Details • Captured Files • Connection Events • Connection Summary Data • Correlation Events • Discovery Events • Host Attributes • Hosts • Intrusion Events • Security Intelligence Events • Servers • White List Events

You can combine fields from...	With fields from...
Host Attributes	• Applications • Correlation Events • Intrusion Events • Connection Summary Data • Application Details • Discovery Events • Connection Events • Hosts • Servers • White List Events
Application Details	• Applications • Host Attributes • Hosts
Discovery Events	• Applications • Host Attributes • Hosts
Connection Events	• Applications • Host Attributes • Hosts • Servers
Security Intelligence Events	• Applications • Host Attributes • Hosts • Servers

You can combine fields from...	With fields from...
Hosts	• Applications • Correlation Events • Intrusion Events • Connection Summary Data • Host Attributes • Application Details • Discovery Events • Connection Events • Servers • White List Events
Servers	• Applications • Intrusion Events • Connection Summary Data • Host Attributes • Connection Events • Hosts
White List Events	• Applications • Host Attributes • Hosts

Sometimes a field in one table maps to more than one field in another table. For example, the predefined **Intrusion Events with Destination Criticality** custom table combines fields from the Intrusion Events table and the Hosts table. Each event in the Intrusion Events table has two IP addresses associated with it—a source IP address and a destination IP address. However, the "events" in the Hosts table each represent a single host IP address (hosts may have multiple IP addresses). Therefore, when you create a custom table based on the Intrusion Events table and the Hosts table, you must choose whether the data you display from the Hosts table applies to the host source IP address or the host destination IP address in the Intrusion Events table.

When you create a new custom table, a default workflow that displays all the columns in the table is automatically created. Also, just as with predefined tables, you can search custom tables for data that you want to use in your network analysis. You can also generate reports based on custom tables, as you can with predefined tables.

User-Defined Custom Tables

Tip Instead of creating a new custom table, you can export a custom table from another Firepower Management Center, then import it onto your Firepower Management Center.

To create a custom table, decide which predefined tables delivered with the Firepower System contain the fields you want to include in your custom table. You can then choose which fields you want to include and, if necessary, configure field mappings for any common fields.

Tip Data involving the Hosts table allows you to view data associated with all IP addresses from one host, rather than one specific IP address.

For example, consider a custom table that combines fields from the Correlation Events table and the Hosts table. You can use this custom table to get detailed information about the hosts involved in violations of any of your correlation policies. Note that you must decide whether to display data from the Hosts table that matches the source IP address or the destination IP address in the Correlation Events table.

If you view the table view of events for this custom table, it displays correlation events, one per row. You can configure the custom table to include the following information:

- the date and time the event was generated
- the name of the correlation policy that was violated
- the name of the rule that triggered the violation
- the IP address associated with the source, or initiating, host involved in the correlation event
- the source host's NetBIOS name
- the operating system and version the source host is running
- the source host criticality

Tip You could create a similar custom table that displays the same information for destination, or responding, hosts.

Creating a Custom Table

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **Create Custom Table**.

Step 3 In the **Name** field, enter a name for the custom table.

Example:

For example, you might enter `Correlation Events with Host Information (Src IP)`.

Step 4 From the **Tables** drop-down list, choose **Correlation Events**.

Step 5 Under **Fields**, choose**Time** and click **Add** to add the date and time when a correlation event was generated.

Step 6 Repeat step 5 to add the **Policy** and **Rule** fields.

Tip You can use Ctrl or Shift while clicking to choose multiple fields. You can also click and drag to choose multiple adjacent values. However, if you want to specify the order the fields appear in the table view of events associated with the table, add the fields one at a time.

Step 7 From the **Tables** drop-down list, choose **Hosts**.

Step 8 Add the **IP Address**, **NetBIOS Name**, **OS Name**, **OS Version**, and **Host Criticality** fields to the custom table.

Step 9 Under **Common Fields**, next to **Correlation Events**, choose **Source IP**.

Your custom table is configured to display the host information you chose in step 8 for the source, or initiating, hosts involved in correlation events.

Tip You can create a custom table that displays detailed host information for the destination, or responding, hosts involved in a correlation event by following this procedure but choosing **Destination IP** instead of **Source IP**.

Step 10 Click **Save**.

Modifying a Custom Table

In a multidomain deployment, the system displays custom tables created in the current domain, which you can edit. It also displays custom tables created in ancestor domains, which you cannot edit. To view and edit custom tables in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **Edit** ( ) next to the table you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Optionally, remove fields from the table by clicking **Delete** ( ) next to the fields you want to remove.

Note If you delete fields currently in use in reports, the system will prompt you to confirm that you want to remove the sections using those fields from those reports.

Step 4 Make other changes as needed.

Step 5 Click **Save**.

Deleting a Custom Table

In a multidomain deployment, the system displays custom tables created in the current domain, which you can delete. It also displays custom tables created in ancestor domains, which you cannot delete. To delete custom tables in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **Delete** ( ) next to the custom table you want to delete.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Viewing a Workflow Based on a Custom Table

When you create a custom table, the system automatically creates a default workflow for it. The first page of this workflow displays a table view of events. If you include intrusion events in your custom table, the second page of the workflow is the packet view. Otherwise, the second page of the workflow is a hosts page. You can also create your own custom workflows based on your custom table.

Tip If you create a custom workflow based on a custom table, you can specify it as the default workflow for that table.

You can use the same techniques to view events in your custom table that you use for event views based on predefined tables.

In a multidomain deployment, the system displays custom tables created in the current domain, which you can edit. It also displays custom tables created in ancestor domains, which you cannot edit. To view and edit custom tables in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **View** ( ) next to the custom table related to the workflow you want to see.

Searching Custom Tables

In a multidomain deployment, the system displays custom tables created in the current domain, which you can edit. It also displays custom tables created in ancestor domains, which you cannot edit. To view and edit custom tables in a lower domain, switch to that domain.

Step 1 Choose **Analysis** > **Advanced** > **Custom Tables**.

Step 2 Click **View** ( ) next to the custom table you want to search.

Tip To use a different workflow, including a custom workflow, click **(switch workflow)** next the workflow title.

Step 3 Click **Search**.

Tip To search the database for a different kind of event or data, choose it from the table drop-down list.

Step 4 Enter your search criteria in the appropriate fields.

If you enter criteria for multiple fields, the search returns only the records that match search criteria specified for all fields.

Tip Click **Object** (+) next to a search field to use an object as a search criterion.

Step 5 Optionally, if you plan to save the search, you can check the **Private** check box to save the search as private so only you can access it. Otherwise, leave the check box clear to save the search for all users.

Tip If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

Step 6 Optionally, you can save the search to be used again in the future. You have the following options:

- Click **Save** to save the search criteria. The search is visible only to your account if you checked the **Private** check box.
- Click **Save As New** to save a new search or assign a name to a search you created by altering a previously-saved search. The search is saved and visible only to your account if you checked the **Private** check box.

Step 7 Click **Search** to start the search.

Your search results appear in the default workflow for the custom table, constrained by the current time range (if applicable).

PART XXV

Events and Assets

CHAPTER 119

Connection Logging

The following topics describe how to configure the Firepower System to log connections made by hosts on your monitored network:

About Connection Logging

The system can generate logs of the connections its managed devices detect. These logs are called *connection events*. Settings in rules and policies give you granular control over which connections you log, when you log them, and where you store the data. Special connection events, called *Security Intelligence events*, represent connections that were blocked by the reputation-based Security Intelligence feature.

Connection events contain data about the detected sessions. The information available for any individual connection event depends on several factors, but in general includes:

- Basic connection properties: timestamp, source and destination IP address, ingress and egress zones, the device that handled the connection, and so on
- Additional connection properties discovered or inferred by the system: applications, requested URLs, or users associated with the connection, and so on
- Metadata about why the connection was logged: which configuration handled the traffic, whether the connection was allowed or blocked, details about encrypted and decrypted connections, and so on

Log connections according to the security and compliance needs of your organization. When setting up connection logging, keep in mind that the system can log a connection for multiple reasons, and that disabling logging in one place does not mean that matching connections will not be logged.

The information in a connection event depends on several factors, including traffic characteristics, the configuration that ultimately handled the connection, and so on.

Note You can supplement the connection logs gathered by your managed devices with connection data generated from exported NetFlow records. This is especially useful if you have NetFlow-enabled routers or other devices deployed on networks that your Firepower System managed devices cannot monitor.

Related Topics

Netflow Data in the Firepower System, on page 1921

Connections That Are Always Logged

Unless you disable connection event storage, the system automatically saves the following end-of-connection events to the Firepower Management Center database, regardless of any other logging configurations.

Connections Associated with Intrusions

The system automatically logs connections associated with intrusion events, unless the connection is handled by the access control policy's default action.

When an intrusion policy associated with the access control default action generates an intrusion event, the system does *not* automatically log the end of the associated connection. Instead, you must explicitly enable default action connection logging. This is useful for intrusion prevention-only deployments where you do not want to log any connection data.

However, if you enable beginning-of-connection logging for the default action, the system *does* log the end of the connection when an associated intrusion policy triggers, in addition to logging the beginning of the connection.

Connections Associated with File and Malware Events

The system automatically logs connections associated with file and malware events.

Note File events generated by inspecting NetBIOS-SSN (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

Connections Associated with Intelligent Application Bypass

The system automatically logs bypassed and would-have-bypassed connections associated with IAB.

Monitored Connections

The system always logs the ends of connections for monitored traffic, even if the traffic matches no other rules and you do not enable default action logging. For more information, see Logging for Monitored Connections, on page 2356.

Other Connections You Can Log

So that you log only critical connections, enable connection logging on a per-rule basis. If you enable connection logging for a rule, the system logs all connections handled by that rule.

You can also log connections handled by policy default actions. Depending on the rule or default action (and for access control, a rule's inspection configuration), your logging options differ.

Prefilter Policy: Rules and Default Action

You can log connections (including entire plaintext, passthrough tunnels) that you fastpath or block with a prefilter policy.

Prefiltering uses outer-header criteria to handle traffic. For tunnels that you log, the resulting connection events contain information from the outer, encapsulation headers.

For traffic subject to further analysis, logging in the prefilter policy is disabled, although matching connections may still be logged by other configurations. The system performs all further analysis using inner headers, that is, the system independently handles and logs each connection within an allowed tunnel.

SSL Policy: Rules and Default Action

You can log connections that match an SSL rule or SSL policy default action.

For blocked connections, the system immediately ends the session and generates an event. For monitored connections and connections that you pass to access control rules, the system generates an event when the session ends.

Access Control Policy: Security Intelligence Decisions

You can log a connection whenever it is blocked by the reputation-based Security Intelligence feature.

Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blocked by Security Intelligence, but still log the match. Security Intelligence monitoring also allows you to create traffic profiles using Security Intelligence information.

When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately, and that is also stored and pruned separately. So that you can identify the matching IP address in the connection, host icons beside blocked and monitored IP addresses look slightly different in the tables on the pages under the **Analysis** > **Connections** menus.

Access Control Policy: Rules and Default Action

You can log connections that match an access control rule or access control policy default action.

Related Topics

How Rules and Policy Actions Affect Logging, on page 2355

How Rules and Policy Actions Affect Logging

Connection events contain metadata about why the connection was logged, including which configurations handled the traffic. Where you can configure connection logging, rule actions, and policy default actions

determine not only how the system inspects and handles matching traffic, but also when and how you can log details about matching traffic.

Related Topics

Tunnel and Prefilter Rule Components, on page 1342
TLS/SSL Rule Actions, on page 1420
Access Control Rule Actions, on page 1279
Connection and Security Intelligence Event Fields, on page 2371

Logging for Fastpathed Connections

You can log fastpathed connections and non-encrypted tunnels, which includes traffic matching the following rules and actions in the prefilter policy:

- Tunnel rules—**Fastpath** action (logs the outer session)
- Prefilter rules—**Fastpath** action

Fastpathed traffic bypasses the rest of access control and QoS, so connection events for fastpathed connections contain limited information.

Logging for Monitored Connections

The system always logs the ends of connections for traffic matching the following configurations, even if the traffic matches no other rules and you do not enable default action logging:

- Security Intelligence—Block lists set to monitor (also generates a Security Intelligence event)
- SSL rules—**Monitor** action
- Access control rules—**Monitor** action

The system does not generate a separate event each time a single connection matches a Monitor rule. Because a single connection can match multiple Monitor rules, each connection event can include and display information on the first eight Monitor access control rules that the connection matches, as well as the first matching SSL Monitor rule.

Similarly, if you send connection events to an external syslog or SNMP trap server, the system does not send a separate alert each time a single connection matches a Monitor rule. Rather, the alert that the system sends at the end of the connection contains information on the Monitor rules the connection matched.

Logging for Trusted Connections

You can log the beginnings and ends of trusted connections, which includes traffic matching the following rules and actions:

- Access control rules—**Trust** action
- Access control default action—**Trust All Traffic**

Note Although you *can* log trusted connections, we recommend you do not do so because trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

TCP connections detected by a Trust rule on the first packet generate only an end-of-connection event. The system generates the event one hour after the final session packet.

Logging for Blocked Connections

You can log blocked connections, which includes traffic matching the following rules and actions:

- Tunnel rules—**Block**
- Prefilter rules—**Block**
- Prefilter default action—**Block all tunnel traffic**
- Security Intelligence—Block lists not set to Monitor (also generates a Security Intelligence event)
- SSL rules—**Block** and **Block with reset**
- SSL default action—**Block** and **Block with reset**
- Access control rules—**Block**, **Block with reset**, and **Interactive Block**
- Access control default action—**Block All Traffic**

Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Caution Logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for an Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

Beginning vs End-of-Connection Logging for Blocked Connections

When you log a blocked connection, how the system logs it depends on why the connection was blocked; this is important to keep in mind when configuring correlation rules based on connection logs:

- For SSL rules and SSL policy default actions that block encrypted traffic, the system logs **end**-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session.
- For other blocking actions, the system logs **beginning**-of-connection events. Matching traffic is denied without further inspection.

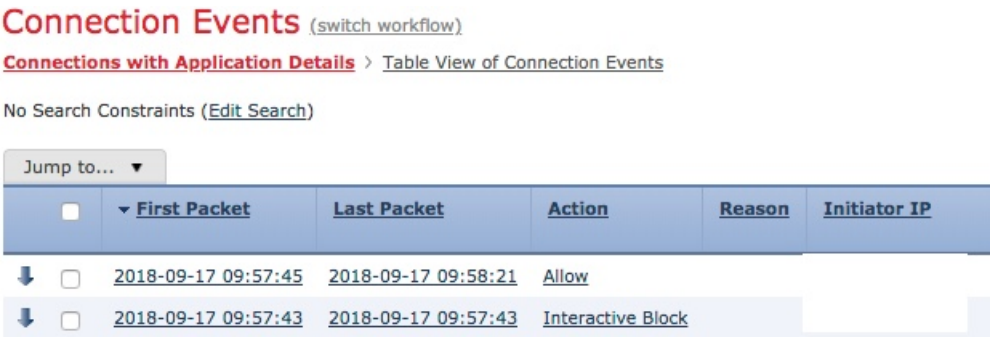
Logging Bypassed Interactive Blocks

Interactive blocking access control rules, which cause the system to display a warning page when a user browses to a prohibited website, allow you to configure end-of-connection logging. This is because if the user clicks through the warning page, the connection is considered a new, allowed connection which the system can monitor and log.

Therefore, for packets that match an Interactive Block or Interactive Block with Reset rule, the system can generate the following connection events:

- A beginning-of-connection event when a user's request is initially blocked and the warning page is displayed; this event has an associated action of `Interactive Block` or `Interactive Block with Reset`
- Multiple beginning- or end-of-connection events if the user clicks through the warning page and loads the originally requested page; these events have an associated action of `Allow` and a reason of `User Bypass`

The following figure shows an example of an interactive block followed by allow.



Logging for Allowed Connections

You can log allowed connections, which includes traffic matching the following rules and actions:

- SSL rules—**Decrypt** action
- SSL rules—**Do not decrypt** action
- SSL default action—**Do not decrypt**
- Access control rules—**Allow** action
- Access control default action—**Network Discovery Only** and any intrusion prevention option

Enabling logging for these configurations ensures the connection is logged, while also permitting (or specifying) the next phase of inspection and traffic handling. SSL logging is always end-of-connection; access control configurations also allow beginning-of-connection logging.

Although the **Analyze** action in tunnel and prefilter rules also allows connections to continue with access control, logging is disabled for rules with this action. Matching connections may still be logged by other configurations. Allowed tunnels might have their encapsulated sessions evaluated and logged individually.

When you allow traffic with an access control rule or default action, you can use an associated intrusion policy to further inspect traffic and block intrusions. For access control rules, you can also use a file policy to detect and block prohibited files, incuding malware. Unless you disable connection event storage, the system automatically logs most allowed connections associated with intrusion, file, and malware events. For detailed information, see Connections That Are Always Logged, on page 2354.

Connections with encrypted payloads are not subject to deep inspection, so connection events for encrypted connections contain limited information.

File and Malware Event Logging for Allowed Connections

When a file policy detects or blocks a file, it logs one of the following events to the Firepower Management Center database:

- *File events*, which represent detected or blocked files, including malware files
- *Malware events*, which represent detected or blocked malware files only
- *Retrospective malware events*, which are generated when the malware disposition for a previously detected file changes

You can disable this logging on a per-access-control-rule basis. You can also disable file and malware event storage entirely.

Note We recommend you leave file and malware event logging enabled.

Beginning vs End-of-Connection Logging

You can log a connection at its beginning or its end, with the following exceptions for blocked traffic:

- Blocked traffic—Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events for blocked traffic. There is no unique end of connection to log.
- Blocked encrypted traffic—When you enable connection logging in an SSL policy, the system logs end-of-connection rather than beginning-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session, and thus cannot immediately block encrypted sessions.

To optimize performance, log either the beginning or the end of any connection, but not both. Monitoring a connection for any reason forces end-of-connection logging. For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session.

The following table details the differences between beginning and end-of-connection events, including the advantages to logging each.

Table 314: Comparing Beginning and End-of-Connection Events

	Beginning-of-Connection Events	**End-of-Connection Events**
Can be generated...	When the system detects the beginning of a connection (or, after the first few packets if event generation depends on application or URL identification)	When the system: • Detects the close of a connection • Does not detect the end of a connection after a period of time • Can no longer track the session due to memory constraints
Can be logged for...	All connections except those blocked by the SSL policy	Most connections

	Beginning-of-Connection Events	End-of-Connection Events
Contain...	Only information that can be determined in the first packet (or the first few packets, if event generation depends on application or URL identification)	All information in the beginning-of-connection event, plus information determined by examining traffic over the duration of the session; for example, the total amount of data transmitted or the timestamp of the last packet in the connection
Are useful...	If you want to log: • Blocked connections • Only the beginning of a connection because the end-of-connection information does not matter to you	If you want to: • Log encrypted connections handled by an SSL policy • Perform any kind of detailed analysis on, or trigger correlation rules using, information collected over the duration of the session • View connection summaries (aggregated connection data) in custom workflows, view connection data in graphical format, or create and use traffic profiles

Firepower Management Center vs External Logging

If you store connection and Security Intelligence event logs on the Firepower Management Center, you can use the Firepower System's reporting, analysis, and data correlation features. For example:

- Dashboards and the Context Explorer provide you with graphical, at-a-glance views of the connections logged by the system.
- Event views (most of the options available under the Analysis menu) present detailed information on the connections logged by the system, which you can display in a graphical or tabular format or summarize in a report.
- Traffic profiling uses connection data to create a profile of your normal network traffic that you can then use as a baseline against which to detect and track anomalous behavior.
- Correlation policies allow you to generate events and trigger responses (such as alerts or external remediations) to specific types of connections or traffic profile changes.

The number of events the Firepower Management Center can store depends on its model.

Note To use these features, you **must** log connections (and in most cases, the end of those connections rather than the beginning). This is why the system automatically logs critical connections—those associated with logged intrusions, prohibited files, and malware.

You can also log events to an external syslog or SNMP trap server, or to other external tools, using the following:

- For external logging on any device:

  A connection you configure called an *alert response*.

- For external logging on FTD devices:

  See About Configuring Syslog, on page 1103 and Configure SNMP Traps, on page 1101.

- For additional options related to external logging:

  See Event Analysis Using External Tools, on page 2257.

Firepower Management Center Alert Responses, on page 2193

Limitations of Connection Logging

You cannot log:

- The outer session of a plaintext, passthrough tunnel whose encapsulated connections are inspected by access control
- TCP connections if the three-way handshake is not completed.

  These connections are not logged as doing so would provide an opportunity for a denial-of-service attack against your Firepower deployment.

  However, you can use the following workaround to monitor or debug failed connections:

  - Use the use **show asp drops** command in the command-line interface.
  - Use the packet capture feature to get more details about these connections. See Packet Capture Overview, on page 355 its and subtopics.

If a connection event does not contain the information you think it should, see Requirements for Populating Connection Event Fields, on page 2387 and Information Available in Connection Event Fields, on page 2389.

When Events Appear in the Event Viewer

The following points are applicable to all types of events:

- If you are looking at a page under the Analysis menu, you must refresh the page to display new events.
- Events generally are available for viewing within a few seconds of the time the traffic was detected. However, there can be an arbitrary delay under situations such as: Exceptionally heavy traffic conditions;

the FMC is managing a lot of devices on a low-bandwidth network; or during operations such as event backup which pause event processing.

Best Practices for Connection Logging

Use the following best practices to ensure that you log *only* the connections you want to log.

So that you log only critical connections, enable connection logging on a per-access-control-rule basis.

Connections that are always logged

The system automatically logs the following:

- Some connections associated with detected files, malware, intrusions, and Intelligent Application Bypass (IAB).

  For more information, see Connections That Are Always Logged, on page 2354.

- Monitored connections.

  For more information, see Logging for Monitored Connections, on page 2356.

Connections to never log

Do not enable logging for the following:

- Access control rules with a Trust action.

  Trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

- Do not enable logging for Block rules in passive deployments. To log connections that the system *would have blocked* if your devices were deployed inline, use a Monitor rule instead of a Block rule.

  Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

- Traffic you're not interested in. Examples follow:
  - Specific allowed traffic, such as DNS requests to a trusted DNS host.
  - Infrastructure traffic that is not related to your service offering.

  (As previously mentioned, you can still monitor this traffic for threats.)

As discussed in Connections That Are Always Logged, on page 2354, even if you disable logging for the preceding, intrusion events, malware, and IAB are still logged.

Avoid logging what's being logged elsewhere

If another device or service is logging connection data for a network segment, disable logging for that segment's data in the Firepower Management Center. Examples follow:

- If a router logs connection events on the same network segment as the Firepower Management Center, avoid logging the same connections on the Firepower Management Center unless you need those connection events for something else, such as correlation policies or traffic profiles.

  For more information about correlation policies, see Introduction to Correlation Policies and Rules, on page 2107. For more information about traffic profiles, see Introduction to Traffic Profiles, on page 2143.

- If you use Stealthwatch to leverage NetFlow records reported from switches and routers to identify potential behavioral anomalies and suspicious traffic patterns, you can disable connection logging for rules monitoring those segments and instead rely on Stealthwatch for behavioral analytics for those parts of your network.

  For more information, consult the Stealthwatch documentation.

Log either the beginning or end of the connection (not both)

If you have a choice between beginning and end-of-connection logging, enable end-of-connection logging. This is because end-of-connection logs information from beginning-of-connection events, as well as information gathered over the duration of the session.

Log the beginning of connections *only* if you want to log blocked connections, or if end-of-connection information does not matter to you.

For more information, see Beginning vs End-of-Connection Logging, on page 2359.

Logging for blocked traffic

Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events.

For more information, see Logging for Blocked Connections, on page 2357.

Log events to an external location

If your company's security policy permits it, you can save disk space on your Firepower Management Center by streaming logs to an external source using any of the following:

- eStreamer, which enables you to stream logs from a Firepower Management Center to a custom-developed client application. For more information, see the *Firepower eStreamer Integration Guide*.
- Syslog or SNMP trap, which are referred to as *alert responses*. For more information, see Firepower Management Center Alert Responses, on page 2193.

Specify the maximum number of event records

Consider the minimum and maximum number of records that can be stored in the database. For example, a virtual Firepower Management Center by default stores 10 million events but the maximum number of events is 50 million. Go to **System** > **Configuration** > **Database** to adjust the size to meet your needs.

For a list of all Firepower Management Center models and their event database sizes, see Database Event Limits, on page 1019.

Control what is displayed in connection events

To specify the number of rows displayed in connection events, click your username in the upper right of the Firepower Management Center and click **User Preferences** > **Event View Settings**. The maximum you can set is 1000 events per page.

Set up connection event reports

To make sure you do not miss connection events, you can set up automated reports in .csv format and optionally schedule them to occur at a regular interval. For more information, see the following:

- Use the report designer (**Analysis** > **Connection** > **Events** > **Report Designer**): About Designing Reports, on page 2171.
- Schedule tasks (**System** > **Tools** > **Scheduling**): About Task Scheduling, on page 197.

Requirements and Prerequisites for Connection Logging

Configure Connection Logging

The following sections describe how to set up connection logging to match various rules and conditions.

Logging Connections with Tunnel and Prefilter Rules

The prefilter policy applies to Firepower Threat Defense devices only.

Before you begin

- Set the rule action to **Block** or **Fastpath**. Logging is disabled for the **Analyze** action, which allows connections to continue with access control, where other configurations determine their handling and logging.
- Logging is performed on inner flows, not on the encapsulating flow.

Step 1 In the prefilter policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both. Because blocked traffic is immediately denied without further inspection, you cannot log end-of-connection events for Block rules.

Step 4 Specify where to send connection events:

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Logging Decryptable Connections with SSL Rules

SSL rules do not apply to NGIPSv devices.

Step 1 In the SSL policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Check **Log at End of Connection**.

For monitored traffic, end-of-connection logging is required.

Step 4 Specify where to send connection events.

Send events to the event viewer if you want to perform Firepower Management Center-based analysis on these connection events. For monitored traffic, this is required.

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Logging Connections with Security Intelligence

The Security Intelligence policy requires the Threat Smart License or Protection Classic License.

Step 1 In the access control policy editor, click **Security Intelligence**.

Step 2 Click **Logging** ( ) to enable Security Intelligenge logging using the following critera:

- By IP address—Click logging next to **Networks**.
- By URL—Click logging next to **URLs**.
- By Domain Name—Click logging next to the **DNS Policy** drop-down list.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Check the **Log Connections** check box.

Step 4 Specify where to send connection and Security Intelligence events.

Send events to the event viewer if you want to perform Firepower Management Center-based analysis, or if you set a Block list to monitor-only.

Step 5 Click **OK** to set logging options.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Logging Connections with Access Control Rules

Depending on your choices for the rule action and deep inspection options, your logging options differ; see How Rules and Policy Actions Affect Logging, on page 2355.

Step 1 In the access control policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click the **Logging** tab.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both.

Step 4 (Optional) Check the **Log Files** check box to log file and malware events associated with the connection.

Cisco recommends you leave this option enabled.

Step 5 Specify where to send the connection events:

- **Event Viewer**: Send connection events to Firepower Management Center web interface if you want to perform Firepower Management Center-based analysis on these connection events, or if the rule action is **Monitor**.
- **Syslog Server**: Send connection events to the syslog server configured in the Logging tab in Access Control Policy, unless overridden.

  Show Overrides: Displays the options to override the settings configured in the access control policy.

  - **Override Severity**: When you choose this option and select a severity for the rule, connection events for this rule will have the selected severity regardless of the severity configured in the Logging tab in Access Control Policy.
  - **Override Default Syslog Destination**: Send the syslog generated for the connection event for this rule to destination specified in this alert.

- **SNMP Trap**: Connection events are sent to the selected SNMP trap.

Step 6 Click **Save** to save the rule.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Logging Connections with a Policy Default Action

A policy's default action determines how the system handles traffic that matches none of the rules in the policy (except Monitor rules in access control and SSL policies, which match and log—but do not handle or inspect—traffic).

Logging settings for the SSL policy default action also govern how the system logs undecryptable sessions.

Before you begin

- For prefilter default action logging, set the default action to **Block all tunnel traffic**. Logging is disabled for the **Allow all tunnel traffic** action, which allows connections to continue with access control, where other configurations determine their handling and logging.

Step 1 In the policy editor, click **Logging** ( ) next to the **Default Action** drop-down list.

Step 2 Specify when you want to log matching connections:

- Log at Beginning of Connection—Not supported for SSL default actions.
- Log at End of Connection—Not supported if you choose the access control **Block All Traffic** default action or the prefilter **Block all tunnel traffic** default action.

To optimize performance, log either the beginning or the end of any connection, but not both.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. In an access control policy, the configuration may also be inherited from an ancestor policy.

Step 3 Specify where to send connection events.

Send events to the event viewer if you want to perform Firepower Management Center-based analysis on these connection events.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

Limiting Logging of Long URLs

End-of-connection events for HTTP traffic record the URL requested by monitored hosts. Disabling or limiting the number of stored URL characters may improve system performance. Disabling URL logging (storing zero characters) does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** () next to **General Settings**.

If **View** () appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Enter the **Maximum URL characters to store in connection events**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 374.

CHAPTER 120

Connection and Security Intelligence Events

The following topics describe how to use connection and security events tables.

About Connection Events

The system can generate logs of the connections its managed devices detect. These logs are called *connection events*. Connection events include *Security Intelligence events* (connections blocked by the reputation-based Security Intelligence feature.)

Connection events generally include transactions detected by:

- Access Control policies
- SSL policies
- Prefilter policies (captured by prefilter or tunnel rules)
- DNS Block lists
- URL Block lists
- Network (IP address) Block lists

Settings in rules and policies give you granular control over which connections you log, when you log them, and where you store the data.

For detailed information, see Connection Logging, on page 2353.

Related Topics

About Security Intelligence, on page 1311

Connection vs. Security Intelligence Events

A *Security Intelligence event* is a connection event that is generated whenever a session is blocked or monitored by the reputation-based Security Intelligence feature.

However, for every Security Intelligence event, there is an identical connection event. You can view and analyze Security Intelligence events independently. The system also stores and prunes Security Intelligence events separately.

Note that the system enforces Security Intelligence before more resource-intensive evaluations. When a connection is blocked by Security Intelligence, the resulting event does not contain the information that the system would have gathered from subsequent evaluation, for example, user identity.

Note In this guide, information about connection events also pertains to Security Intelligence events, unless otherwise noted.

NetFlow Connections

To supplement the connection data gathered by your managed devices, you can use records broadcast by NetFlow exporters to generate connection events. This is especially useful if the NetFlow exporters are monitoring different networks than those monitored by your managed devices.

The system logs NetFlow records as unidirectional end-of-connection events in the Firepower Management Center database. The available information for these connections differs somewhat from connections detected by your access control policy; see Differences between NetFlow and Managed Device Data, on page 1923.

Related Topics

Netflow Data in the Firepower System, on page 1921

Connection Summaries (Aggregated Data for Graphs)

The Firepower System aggregates connection data collected over five-minute intervals into connection summaries, which the system uses to generate connection graphs and traffic profiles. Optionally, you can create custom workflows based on connection summary data, which you use in the same way as you use workflows based on individual connection events.

Note that there are no connection summaries specifically for Security Intelligence events, although corresponding end-of-connection events can be aggregated into connection summary data.

To be aggregated, multiple connections must:

- represent the end of connections
- have the same source and destination IP addresses, and use the same port on the responder (destination) host
- use the same protocol (TCP or UDP)
- use the same application protocol
- either be detected by the same Firepower System managed device or by the same NetFlow exporter

Each connection summary includes total traffic statistics, as well as the number of connections in the summary. Because NetFlow exporters generate unidirectional connections, a summary's connection count is incremented by two for every connection based on NetFlow data.

Note that connection summaries do not contain all of the information associated with the summaries' aggregated connections. For example, because client information is not used to aggregate connections into connection summaries, summaries do not contain client information.

Long-Running Connections

If a monitored session spans two or more five-minute intervals over which connection data is aggregated, the connection is considered a *long-running connection*. When calculating the number of connections in a connection summary, the system increments the count only for the five-minute interval in which a long-running connection was initiated.

Also, when calculating the number of packets and bytes transmitted by the initiator and responder in a long-running connection, the system does not report the number of packets and bytes that were actually transmitted during each five-minute interval. Instead, the system assumes a constant rate of transmission and calculates estimated figures based on the total number of packets and bytes transmitted, the length of the connection, and what portion of the connection occurred during each five-minute interval.

Combined Connection Summaries from External Responders

To reduce the space required to store connection data and speed up the rendering of connection graphs, the system combines connection summaries when:

- one of the hosts involved in the connection is not on your monitored network
- other than the IP address of the external host, the connections in the summaries meet the summary aggregation criteria

When viewing connection summaries in the Analysis > Connections submenu pages, and when working with connection graphs, the system displays `external` instead of an IP address for the non-monitored hosts.

As a consequence of this aggregation, if you attempt to drill down to the table view of connection data (that is, access data on individual connections) from a connection summary or graph that involves an external responder, the table view contains no information.

Connection and Security Intelligence Event Fields

Note You cannot use the connection/Security Intelligence events Search page to search for events associated with a connection.

Access Control Policy (Syslog: ACPolicy)

The access control policy that monitored the connection.

Access Control Rule (Syslog: AccessControlRuleName)

The access control rule or default action that handled the connection, as well as up to eight Monitor rules matched by that connection.

If the connection matched one Monitor rule, the Firepower Management Center displays the name of the rule that handled the connection, followed by the Monitor rule name. If the connection matched more than one Monitor rule, the number of matching Monitor rules is displayed, for example, `Default Action + 2 Monitor Rules`.

To display a pop-up window with a list of the first eight Monitor rules matched by the connection, click ***N* Monitor Rules**.

Action (Syslog: AccessControlRuleAction)

The action associated with the configuration that logged the connection.

For Security Intelligence-monitored connections, the action is that of the first non-Monitor access control rule triggered by the connection, or the default action. Similarly, because traffic matching a Monitor rule is always handled by a subsequent rule or by the default action, the action associated with a connection logged due to a Monitor rule is never Monitor. However, you can still trigger correlation policy violations on connections that match Monitor rules.

Action	Description
Allow	Connections either allowed by access control explicitly, or allowed because a user bypassed an interactive block.
Block, Block with reset	Blocked connections, including: • tunnels and other connections blocked by the prefilter policy • connections blocked by Security Intelligence • encrypted connections blocked by an SSL policy • connections where an exploit was blocked by an intrusion policy • connections where a file (including malware) was blocked by a file policy For connections where the system blocks an intrusion or file, system displays `Block`, even though you use access control Allow rules to invoke deep inspection.
Fastpath	Non-encrypted tunnels and other connections fastpathed by the prefilter policy.
Interactive Block, Interactive Block with reset	Connections logged when the system initially blocks a user's HTTP request using an Interactive Block rule. If the user clicks through the warning page that the system displays, additional connections logged for the session have an action of Allow.
Trust	Connections trusted by access control. The system logs trusted TCP connections differently depending on the device model.
Default Action	Connections handled by the access control policy's default action.
(Blank/empty)	The connection closed before enough packets had passed to match a rule. This can happen only if a facility other than access control, such as intrusion prevention, causes the connection to be logged.

Application Protocol (Syslog: ApplicationProtocol)

In the Firepower Management Center web interface, this value constrains summaries and graphs.

The application protocol, which represents communications between hosts, detected in the connection.

Application Protocol Category and Tag

Criteria that characterize the application to help you understand the application's function.

Application Risk

The risk associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated risk; this field displays the highest of those.

Business Relevance

The business relevance associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those.

Client and Client Version (Syslog: Client, ClientVersion)

The client application and version of that client detected in the connection.

If the system cannot identify the specific client used in the connection, the field displays the word "client" appended to the application protocol name to provide a generic name, for example, FTP client.

Client Category and Tag

Criteria that characterize the application to help you understand the application's function.

Connection Counter (Syslog Only)

A counter that distinguishes one connection from another simultaneous connection. This field has no significance on its own.

The following fields collectively uniquely identify a connection event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Connection Instance ID (Syslog Only)

The Snort instance that processed the connection event. This field has no significance on its own.

The following fields collectively uniquely identify a connection event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

ConnectionDuration (Syslog Only)

This field exists ONLY as a syslog field; it does not exist in the Firepower Management Center web interface. (The web interface conveys this information using the First Packet and Last Packet columns.)

This field has a value only when logging occurs at the end of the connection. For a start-of-connection syslog message, this field is not output, as it is not known at that time.

For an end-of-connection syslog message, this field indicates the number of seconds between the first packet and the last packet, which may be zero for a short connection. For example, if the timestamp of the syslog is 12:34:56 and the ConnectionDuration is 5, then the first packet was seen at 12:34:51.

Connections

The number of connections in a connection summary. For long-running connections, that is, connections that span multiple connection summary intervals, only the first connection summary interval is incremented. To view meaningful results for searches using the **Connections** criterion, use a custom workflow that has a connection summary page.

Count

The number of connections that match the information that appears in each row. Note that the **Count** field appears only after you apply a constraint that creates two or more identical rows. If you create a custom workflow and do not add the **Count** column to a drill-down page, each connection is listed individually and packets and bytes are not summed.

Destination Port/ICMP Code (Syslog: Separate fields - DstPort, ICMPCode)

In the Firepower Management Center web interface, these values constrain summaries and graphs.

The port or ICMP code used by the session responder.

DestinationSecurityGroup (Syslog Only)

This field holds the text value associated with the numeric value in **DestinationSecurityGroupTag**, if available. If the group name is not available as a text value, then this field contains the same integer value as the DestinationSecurityGroupTag field.

Destination SGT (Syslog: DestinationSecurityGroupTag)

The numeric Security Group Tag (SGT) attribute of the destination involved in the connection.

The Destination SGT value is obtained from ISE only, from either SXP or from a user session.

Detection Type

This field shows the source of detection of a client.

Device

In the Firepower Management Center web interface, this value constrains summaries and graphs.

The managed device that detected the connection or, for connections generated from NetFlow data, the managed device that processed the data.

DeviceUUID (Syslog Only)

The unique identifier of the Firepower device that generated an event.

The following fields collectively uniquely identify a connection event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

DNS Query (Syslog: DNSQuery)

The DNS query submitted in a connection to the name server to look up a domain name.

DNS Record Type (Syslog: DNSRecordType)

The type of the DNS resource record used to resolve a DNS query submitted in a connection.

DNS Response (Syslog: DNSResponseType)

The DNS response returned in a connection to the name server when queried.

DNS Sinkhole Name (Syslog: DNS_Sinkhole)

The name of the sinkhole server where the system redirected a connection.

DNS TTL (Syslog: DNS_TTL)

The number of seconds a DNS server caches the DNS resource record.

Domain

The domain of the managed device that detected the connection or, for connections generated from NetFlow data, the domain of the managed device that processed the data. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Endpoint Location

The IP address of the network device that used ISE to authenticate the user, as identified by ISE.

Endpoint Profile (Syslog: Endpoint Profile)

The user's endpoint device type, as identified by ISE.

Event Priority (Syslog Only)

Whether or not the connection event is a high priority event. `High` priority events are connection events that are associated with an intrusion, Security Intelligence, file, or malware event. All other events are `Low` priority.

Files (Syslog: FileCount)

The number of files (including malware files) detected or blocked in a connection associated with one or more file events.

In the Firepower Management Center web interface, the **View Files icon** links to a list of files. The number on the icon indicates the number of files (including malware files) detected or blocked in that connection.

First Packet or Last Packet (Syslog: See the ConnectionDuration field)

The date and time the first or last packet of the session was seen.

First Packet Time (Syslog Only)

The time the system encountered the first packet.

The following fields collectively uniquely identify a connection event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

HTTP Referrer (Syslog: HTTPReferer)

The HTTP referrer, which represents the referrer of a requested URL for HTTP traffic detected in the connection (such as a website that provided a link to, or imported a link from, another URL).

HTTP Response Code (Syslog: HTTPResponse)

The HTTP status code sent in response to a client's HTTP request over a connection.

Ingress/Egress Interface (Syslog: IngressInterface, EgressInterface)

The ingress or egress interface associated with the connection. If your deployment includes an asymmetric routing configuration, the ingress and egress interface may not belong to the same inline pair.

Ingress/Egress Security Zone (Syslog: IngressZone, EgressZone)

The ingress or egress security zone associated with the connection.

For rezoned encapsulated connections, the ingress field displays the tunnel zone you assigned, instead of the original ingress security zone. The egress field is blank.

Initiator/Responder Bytes (Syslog: InitiatorBytes, ResponderBytes)

The total number of bytes transmitted by the session initiator or received by the session responder.

Initiator/Responder Continent

When a routable IP is detected, the continent associated with the IP address for the session initiator or responder.

Initiator/Responder Country

When a routable IP is detected, the country associated with the IP address of the session initiator or responder. The system displays an icon of the country's flag, and the country's ISO 3166-1 alpha-3 country code. Hover your pointer over the flag icon to view the country's full name.

Initiator/Responder IP (Syslog: SrcIP, DstIP)

In the Firepower Management Center web interface, these values constrain summaries and graphs.

The IP address (and host name, if DNS resolution is enabled) of the session initiator or responder.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

In the Firepower Management Center web interface, the host icon identifies the IP address that caused the connection to be blocked.

For plaintext, passthrough tunnels either blocked or fastpathed by the prefilter policy, initiator and responder IP addresses represent the tunnel endpoints—the routed interfaces of the network devices on either side of the tunnel.

Initiator/Responder Packets (Syslog: InitiatorPackets, ResponderPackets)

The total number of packets transmitted by the session initiator or received by the session responder.

Initiator User (Syslog: User)

In the Firepower Management Center web interface, this value constrains summaries and graphs.

The user logged into the session initiator. If this field is populated with **No Authentication**, the user traffic:

- matched an access control policy without an associated identity policy
- did not match any rules in the identity policy

If applicable, the username is preceded by `<realm>\`.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

Intrusion Events (Syslog: IPSCount)

The number of intrusion events, if any, associated with the connection.

In the Firepower Management Center web interface, the **View Intrusion Events icon** links to a list of events.

IOC

Whether the event triggered an indication of compromise (IOC) against a host involved in the connection.

NetBIOS Domain (Syslog: NetBIOSDomain)

The NetBIOS domain used in the session.

NetFlow SNMP Input/Output

For connections generated from NetFlow data, the interface index for the interface where connection traffic entered or exited the NetFlow exporter.

NetFlow Source/Destination Autonomous System

For connections generated from NetFlow data, the border gateway protocol autonomous system number for the source or destination of traffic in the connection.

NetFlow Source/Destination Prefix

For connections generated from NetFlow data, the source or destination IP address ANDed with the source or destination prefix mask.

NetFlow Source/Destination TOS

For connections generated from NetFlow data, the setting for the type-of-service (TOS) byte when connection traffic entered or exited the NetFlow exporter.

Network Analysis Policy (Syslog: NAPPolicy)

The network analysis policy (NAP), if any, associated with the generation of the event.

Original Client Country

The country where the original client IP address belongs. To obtain this value, the system extracts the original client IP address from an X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header, then maps it to the country using the geolocation database (GeoDB). To populate this field, you must enable an access control rule that handles proxied traffic based on its original client.

Original Client IP (Syslog: originalClientSrcIP)

The original client IP address from an X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header. To populate this field, you must enable an access control rule that handles proxied traffic based on its original client.

Prefilter Policy (Syslog: Prefilter Policy)

The prefilter policy that handled the connection.

Protocol (Syslog: Protocol)

In the Firepower Management Center web interface:

- This value constrains summaries and graphs.
- This field is available only as a search field.

The transport protocol used in the connection. To search for a specific protocol, use the name or number protocol as listed in http://www.iana.org/assignments/protocol-numbers.

QoS-Applied Interface

For rate-limited connections, the name of the interface where you applied rate limiting.

QoS-Dropped Initiator/Responder Bytes

The number of bytes dropped from the session initiator or session responder due to rate limiting.

QoS-Dropped Initiator/Responder Packets

The number of packets dropped from the session initiator or session responder due to rate limiting.

QoS Policy

The QoS policy that rate limited the connection.

QoS Rule

The QoS rule that rate limited the connection.

Reason (Syslog: AccessControlRuleReason)

The reason or reasons the connection was logged, in many situations. For a full list, see Connection Event Reasons, on page 2386.

Connections with a Reason of IP Block, DNS Block, and URL Block have a threshold of 15 seconds per unique initiator-responder pair. After the system blocks one of those connections, it does not generate connection events for additional blocked connections between those two hosts for the next 15 seconds, regardless of port or protocol.

Referenced Host (Syslog: ReferencedHost)

If the protocol in the connection is HTTP or HTTPS, this field displays the host name that the respective protocol was using.

Security Context (Syslog: Context)

For connections handled by ASA FirePOWER in multiple context mode, the metadata identifying the virtual firewall group through which the traffic passed.

Security Intelligence Category (Syslog: URLSICategory, DNSSICategory)

The name of the object that represents or contains the blocked URL, domain, or IP address in the connection. The Security Intelligence category can be the name of a network object or group, a Block list, a custom Security Intelligence list or feed, a TID category related to an observation, or one of the categories in the Intelligence Feed.

In the Firepower Management Center web interface, DNS, Network (IP address), and URL Security Intelligence connection events are combined into a single category field. In syslog messages, those events are specific by type.

For more information about the categories in the Intelligence Feed, see Security Intelligence Categories, on page 1317.

Source Device

In the Firepower Management Center web interface, this value constrains summaries and graphs.

The IP address of the NetFlow exporter that broadcast the data used to generate for the connection. If the connection was detected by a managed device, this field displays `Firepower`.

Source Port/ICMP Type (Syslog: SrcPort, ICMPType)

In the Firepower Management Center web interface, these values constrain summaries and graphs.

The port or ICMP type used by the session initiator.

SourceSecurityGroup (Syslog Only)

This field holds the text value associated with the numeric value in **SourceSecurityGroupTag**, if available. If the group name is not available as a text value, then this field contains the same integer value as the SourceSecurityGroupTag field. Tags can be obtained from inline devices (no source SGT name specified) or from ISE (which specifies a source).

Source SGT (Syslog: SourceSecurityGroupTag)

The numeric representation of the Security Group Tag (SGT) attribute of the packet involved in the connection. The SGT specifies the privileges of a traffic source within a trusted network. Security Group Access (a feature of both Cisco TrustSec and Cisco ISE) applies the attribute as packets enter the network.

SSL Actual Action (Syslog: SSLActualAction)

In the Firepower Management Center web interface, this field is a search field only.

The system displays field values in the **SSL Status** field on search workflow pages.

The action the system applied to encrypted traffic in the SSL policy.

Action	Description
Block/Block with reset	Represents blocked encrypted connections.
Decrypt (Resign)	Represents an outgoing connection decrypted using a re-signed server certificate.
Decrypt (Replace Key)	Represents an outgoing connection decrypted using a self-signed server certificate with a substituted public key.
Decrypt (Known Key)	Represents an incoming connection decrypted using a known private key.
Default Action	Indicates the connection was handled by the default action.
Do not Decrypt	Represents a connection the system did not decrypt.

SSL Certificate Information (Syslog: SSLCertificate)

In the Firepower Management Center web interface, this field is a search field only.

The information stored on the public key certificate used to encrypt traffic, including:

- Subject/Issuer Common Name
- Subject/Issuer Organization
- Subject/Issuer Organization Unit
- Not Valid Before/After
- Serial Number
- Certificate Fingerprint
- Public Key Fingerprint

SSL Certificate Status (Syslog: SSLServerCertStatus)

This applies only if you configured a Certificate Status SSL rule condition. If encrypted traffic matches an SSL rule, this field displays one or more of the following server certificate status values:

- Self Signed
- Valid
- Invalid Signature

- Invalid Issuer
- Expired
- Unknown
- Not Valid Yet
- Revoked

If undecryptable traffic matches an SSL rule, this field displays `Not Checked`.

SSL Cipher Suite (Syslog: SSSLCipherSuite)

A macro value representing a cipher suite used to encrypt the connection. See www.iana.org/assignments/tls-parameters/tls-parameters.xhtml for cipher suite value designations.

SSL Encryption applied to the connection

This field is available only as a search field in the Firepower Management Center web interface.

Enter **`yes`** or **`no`** in the **SSL** search field to view TLS/SSL-encrypted or non-encrypted connections.

SSL Expected Action (Syslog: SSLExpectedAction)

In the Firepower Management Center web interface, this field is a search field only.

The action the system expected to apply to encrypted traffic, given the SSL rules in effect.

Enter any of the values listed for **SSL Actual Action**.

SSL Failure Reason (Syslog: SSLFlowStatus)

The reason the system failed to decrypt encrypted traffic:

- Unknown
- No Match
- Success
- Uncached Session
- Unknown Cipher Suite
- Unsupported Cipher Suite
- Unsupported SSL Version
- SSL Compression Used
- Session Undecryptable in Passive Mode
- Handshake Error
- Decryption Error
- Pending Server Name Category Lookup
- Pending Common Name Category Lookup
- Internal Error
- Network Parameters Unavailable

- Invalid Server Certificate Handle
- Server Certificate Fingerprint Unavailable
- Cannot Cache Subject DN
- Cannot Cache Issuer DN
- Unknown SSL Version
- External Certificate List Unavailable
- External Certificate Fingerprint Unavailable
- Internal Certificate List Invalid
- Internal Certificate List Unavailable
- Internal Certificate Unavailable
- Internal Certificate Fingerprint Unavailable
- Server Certificate Validation Unavailable
- Server Certificate Validation Failure
- Invalid Action

Field values are displayed in the **SSL Status** field on the search workflow pages.

SSL Flow Error

The error name and hexadecimal code if an error occurred during the TLS/SSL session; `Success` if no error occurred.

SSL Flow Flags

The first ten debugging level flags for an encrypted connection. On a workflow page, to view all flags, click the ellipsis (**...**).

The message OVER_SUBSCRIBED is displayed if your managed device is overloaded. For more information, see Troubleshoot TLS/SSL Oversubscription, on page 1447.

SSL Flow Messages

The keywords below indicate encrypted traffic is associated with the specified message type exchanged between client and server during the TLS/SSL handshake. See http://tools.ietf.org/html/rfc5246 for more information.

- HELLO_REQUEST
- CLIENT_ALERT
- SERVER_ALERT
- CLIENT_HELLO
- SERVER_HELLO
- SERVER_CERTIFICATE
- SERVER_KEY_EXCHANGE

- CERTIFICATE_REQUEST
- SERVER_HELLO_DONE
- CLIENT_CERTIFICATE
- CLIENT_KEY_EXCHANGE
- CERTIFICATE_VERIFY
- CLIENT_CHANGE_CIPHER_SPEC
- CLIENT_FINISHED
- SERVER_CHANGE_CIPHER_SPEC
- SERVER_FINISHED
- NEW_SESSION_TICKET
- HANDSHAKE_OTHER
- APP_DATA_FROM_CLIENT
- APP_DATA_FROM_SERVER

The message HEARTBEAT is displayed if applications are using the TLS/SSL heartbeat extension. For more information, see About TLS Heartbeat, on page 1449.

SSL Policy (Syslog: SSLPolicy)

The SSL policy that handled the connection.

SSL Rule (Syslog: SSLRuleName)

The SSL rule or default action that handled the connection, as well as the first Monitor rule matched by that connection. If the connection matched a Monitor rule, the field displays the name of the rule that handled the connection, followed by the Monitor rule name.

SSLServerName (Syslog Only)

This field exists ONLY as a syslog field; it does not exist in the Firepower Management Center web interface.

Hostname of the server with which the client established an encrypted connection.

SSL Session ID (Syslog: SSLSessionID)

The hexadecimal Session ID negotiated between the client and server during the TLS/SSL handshake.

SSL Status

The action associated with the **SSL Actual Action** (SSL rule, default action, or undecryptable traffic action) that logged the encrypted connection. The **Lock icon** links to SSL certificate details. If the certificate is unavailable (for example, for connections blocked due to TLS/SSL handshake error), the lock icon is dimmed.

If the system fails to decrypt an encrypted connection, it displays the **SSL Actual Action** (undecryptable traffic action) taken, as well as the **SSL Failure Reason**. For example, if the system detects traffic encrypted with an unknown cipher suite and allows it without further inspection, this field displays `Do Not Decrypt (Unknown Cipher Suite)`.

When searching this field, enter one or more of the **SSL Actual Action** and **SSL Failure Reason** values to view encrypted traffic the system handled or failed to decrypt.

SSL Subject/Issuer Country

This field is available only in the Firepower Management Center web interface, and only as a search field.

A two-character ISO 3166-1 alpha-2 country code for the subject or issuer country associated with the encryption certificate.

SSL Ticket ID (Syslog: SSLTicketID)

A hexadecimal hash value of the session ticket information sent during the TLS/SSL handshake.

SSLURLCategory (Syslog Only)

URL categories for the URL visited in the encrypted connection.

This field exists ONLY as a syslog field; in the Firepower Management Center web interface, values in this field are included in the URL Category column.

See also **URL**.

SSL Version (Syslog: SSLVersion)

The TLS/SSL protocol version used to encrypt the connection:

- Unknown
- SSLv2.0
- SSLv3.0
- TLSv1.0
- TLSv1.1
- TLSv1.2

TCP Flags (Syslog: TCPFlags)

For connections generated from NetFlow data, the TCP flags detected in the connection.

When searching this field, enter a list of comma-separated TCP flags to view all connections that have *at least* one of those flags.

Time

The ending time of the five-minute interval that the system used to aggregate connections in a connection summary. This field is not searchable.

TLS Fingerprint Process Name

Process or client in the TLS client hello packet that was analyzed by the encrypted visibility engine.

TLS Fingerprint Confidence Score

The confidence value in the range 0-100% that the encrypted visibility engine has detected the right process. For example, if the process name is Firefox and if the confidence score is 80%, it means that the engine is 80% confident that the process it has detected is Firefox.

TLS Fingerprint Malware Confidence

The probability level that the process detected by the encrypted visibility engine contains malware. This field indicates the bands (Very High, High, Medium, Low, or Very Low) based on the value in the malware confidence score.

TLS Fingerprint Malware Confidence Score

The confidence value in the range 0-100% that the process detected by the encrypted visibility engine contains malware. If the malware confidence score is very high, say 90%, then the TLS fingerprint Process Name field will display "Malware."

Total Packets

This field is available only as a search field.

The total number of packets transmitted in the connection.

Traffic (KB)

This field is available only as a search field.

The total amount of data transmitted in the connection, in kilobytes.

Tunnel/Prefilter Rule (Syslog: Tunnel or Prefilter Rule)

The tunnel rule, prefilter rule, or prefilter policy default action that handled the connection.

URL, URL Category, and URL Reputation (Syslog: URL, URLCategory and SSLURLCategory, URLReputation)

The URL requested by the monitored host during the session and its associated category and reputation, if available.

If the system identifies or blocks a TLS/SSL application, the requested URL is in encrypted traffic, so the system identifies the traffic based on an SSL certificate. For TLS/SSL applications, therefore, this field indicates the common name contained in the certificate.

See also **SSLURLCategory**, above.

User Agent (Syslog: UserAgent)

The user-agent string application information extracted from HTTP traffic detected in the connection.

VLAN ID (Syslog: VLAN_ID)

The innermost VLAN ID associated with the packet that triggered the connection.

Web Application (Syslog: WebApplication)

The web application, which represents the content or requested URL for HTTP traffic detected in the connection.

If the web application does not match the URL for the event, the traffic is probably referred traffic, such as advertisement traffic. If the system detects referred traffic, it stores the referring application (if available) and lists that application as the web application.

If the system cannot identify the specific web application in HTTP traffic, this field displays `Web Browsing`.

Web Application Category and Tag

Criteria that characterize the application to help you understand the application's function.

About Connection and Security Intelligence Event Fields

In the Firepower Management Center web interface, you can view and search connection and security intelligence events using tabular and graphical workflows under the **Analysis > Connections** submenus.

Note For each Security Intelligence event, there is an identical, separately stored connection event. All Security Intelligence events have a populated **Security Intelligence Category** field.

The information available for any individual event can vary depending on how, why, and when the system logged the connection.

Search Constraints

Fields marked with an asterisk (*****) on search pages constrain connection graphs and connection summaries. Because connection graphs are based on connection summaries, the same criteria that constrain connection summaries also constrain connection graphs. If you search connection summaries using invalid search constraints and view your results using a connection summary page in a custom workflow, the invalid constraints are labeled as not applicable (N/A) and are marked with a strikethrough.

Syslog Fields

Most fields appear both in the Firepower Management Center web interface and as syslog messages. Fields without a listed syslog equivalent are not available in syslog messages. A few fields are syslog-only, as noted, and few others are separate fields in syslog messages but are consolidated fields in the web interface or vice-versa.

A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields

Table 315: Comparison of Terms

Fields	Event Type	Description
Initiator/Responder	Connection	Initiator/responder of the connection. The initiator of a connection is not necessarily the same as the source of an intrusion or the sender of a malware file.
Source/Destination	Intrusion	Source/destination of the attack. The source of an intrusion event can be the initiator or the responder of the connection.
Sender/Receiver (Sending..., Receiving...)	File, Malware	Sender/receiver of a file or malware. The sender of a file is not necessarily the initiator of the connection, as a file may be uploaded or downloaded.

Connection Event Reasons

The Reason field in a connection event displays the reason or reasons the connection was logged, in the following situations:

Reason	Description
Content Restriction	The system modified the packet to enforce content restrictions related to either the Safe Search or YouTube EDU feature.
DNS Block	The system denied the connection without inspection, based on the domain name and Security Intelligence data. A reason of DNS Block is paired with an action of Block, Domain not found, or Sinkhole, depending on the DNS rule action.
DNS Monitor	The system would have denied the connection based on the domain name and Security Intelligence data, but you configured the system to monitor, rather than deny, the connection.
File Block	The connection contained a file or malware file that the system prevented from being transmitted. A reason of File Block is always paired with an action of Block.
File Custom Detection	The connection contained a file on the custom detection list that the system prevented from being transmitted.
File Monitor	The system detected a particular type of file in the connection.
File Resume Allow	File transmission was originally blocked by a Block Files or Block Malware file rule. After a new access control policy allowing the file was deployed, the HTTP session automatically resumed. This reason only appears in inline deployments.
File Resume Block	File transmission was originally allowed by a Detect Files or Malware Cloud Lookup file rule. After a new access control policy blocking the file was deployed, the HTTP session automatically stopped. This reason only appears in inline deployments.
Intelligent App Bypass	The Intelligent Application Bypass (IAB) mode: • If the action is Trust, IAB was in bypass mode. Matching traffic passed without further inspection. • If the action is Allow, IAB was in test mode. Matching traffic was available for further inspection.
Intrusion Block	The system blocked or would have blocked an exploit (intrusion policy violation) detected in the connection. A reason of Intrusion Block is paired with an action of Block for blocked exploits and Allow for would-have-blocked exploits.
Intrusion Monitor	The system detected, but did not block, an exploit detected in the connection. This occurs when the state of the triggered intrusion rule is set to Generate Events.
IP Block	The system denied the connection without inspection, based on the IP address and Security Intelligence data. A reason of IP Block is always paired with an action of Block.

Reason	Description
IP Monitor	The system would have denied the connection based on the IP address and Security Intelligence data, but you configured the system to monitor, rather than deny, the connection.
SSL Block	The system blocked an encrypted connection based on the TLS/SSL inspection configuration. A reason of SSL Block is always paired with an action of Block.
URL Block	The system denied the connection without inspection, based on the URL and Security Intelligence data. A reason of URL Block is always paired with an action of Block.
URL Monitor	The system would have denied the connection based on the URL and Security Intelligence data, but you configured the system to monitor, rather than deny, the connection.
User Bypass	The system initially blocked a user's HTTP request, but the user clicked through a warning page to view the site. A reason of User Bypass is always paired with an action of Allow.

Requirements for Populating Connection Event Fields

The information available for a connection event, Security Intelligence event, or connection summary depends on several factors.

Appliance Model and License

Many features require that you enable specific licensed capabilities on target devices, and many features are only available on some models.

For example, NGIPSv devices do not support TLS/SSL inspection. They cannot inspect encrypted traffic; logged connection events do not contain information about encrypted connections.

Traffic Characteristics

The system only reports information present (and detectable) in network traffic. For example, there could be no user associated with an initiator host, or no referenced host detected in a connection where the protocol is not DNS, HTTP, or HTTPS.

Origin/Detection Method: Traffic-Based Detection vs NetFlow

With the exception of NetFlow-only fields, the information available in NetFlow records is more limited than the information generated by traffic-based detection; see Differences between NetFlow and Managed Device Data, on page 1923.

Evaluation Stage

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance.

For example, the system enforces Security Intelligence before more resource-intensive evaluations. When a connection is blocked by Security Intelligence, the resulting event does not contain the information that the system would have gathered from subsequent evaluation, for example, user identity.

Logging Method: Beginning or End of Connection

When the system detects a connection, whether you can log it at its beginning or its end (or both) depends on how you configure the system to detect and handle it.

Beginning-of-connection events do not have information that must be determined by examining traffic over the duration of the session (for example, the total amount of data transmitted or the timestamp of the last packet in the connection). Beginning-of-connection events are also not guaranteed to have information about application or URL traffic in the session, and do not contain any details about the session's encryption. Beginning-of-connection logging is usually the only option for blocked connections.

Connection Event Type: Individual vs Summary

Connection summaries do not contain all of the information associated with their aggregated connections. For example, because client information is not used to aggregate connections into connection summaries, summaries do not contain client information.

Keep in mind that connection graphs are based on connection summary data, which use only end-of-connection logs. If your system is configured to log only beginning-of-connection data, connection graphs and connection summary event views contain no data.

Other Configurations

Other configurations that affect connection logging include, but are not limited to:

- ISE-related fields are populated only if you configure ISE, in connections associated with users who authenticate via an Active Directory domain controller. Connection events do not contain ISE data for users who authenticate via LDAP, RADIUS, or RSA domain controllers.
- The Security Group Tag (SGT) fields are populated only if you configure ISE as an identity source or add custom SGT rule conditions.
- Prefilter-related fields (including tunnel zone information in security zone fields) are populated only in connections handled by a prefilter policy.
- TLS/SSL-related fields are populated only in encrypted connections handled by an SSL policy. You can view the values of the fields using a Do Not Decrypt rule action if you do not need to decrypt the traffic.
- File information fields are populated only in connections logged by access control rules associated with file policies.
- Intrusion information fields are populated only in connections logged by access control rules either associated with intrusion policies or using the default action.
- QoS-related fields are populated only in connections subject to rate limiting.
- The Reason field is populated only in specific situations, such as when a user bypasses an Interactive Block configuration.
- The Domain field is only present if you have ever configured the Firepower Management Center for multitenancy.
- An advanced setting in the access control policy controls the number of characters the system stores in the connection log for each URL requested by monitored hosts in HTTP sessions. If you use this setting to disable URL logging, the system does not display individual URLs in the connection log, although you can still view category and reputation data, if it exists.

Related Topics

Differences between NetFlow and Managed Device Data, on page 1923

Information Available in Connection Event Fields

The table in this topic indicates when the system can populate connection and Security Intelligence fields. The columns in the table represent the following event types:

- Origin: Direct—Events that represent connections detected and handled by a Firepower System managed device.
- Origin: NetFlow—Events that represent connections exported by a NetFlow exporter.
- Logging: Start—Events that represent connections logged at their beginning.
- Logging: End—Events that represent connections logged at their end.

A "yes" in the table does not mean that the system must populate a connection event field, rather, that it can. The system only reports information present (and detectable) in network traffic. For example, TLS/SSL-related fields are populated only for records of encrypted connections handled by an SSL policy.

Connection Event Field	Origin: Direct	Origin: NetFlow	Logging: Start	Logging: End

Using Connection and Security Intelligence Event Tables

You can use the Firepower Management Center to view a table of connection or Security Intelligence events. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access connection graphs differs depending on the workflow you use. You can use a predefined workflow, which terminates in a table view of events. You can also create a custom workflow that displays only the information that matches your specific needs.

When you are using a connection or Security Intelligence workflow table, you can perform many common actions.

Note that when you constrain connection events on a drill-down page, the packets and bytes from identical events are summed. However, if you are using a custom workflow and did not add a **Count** column to a drill-down page, the events are listed individually and packets and bytes are not summed.

Note that **Connection Events** table view displays **1 of Many** instead of how many pages of events are available if your system generates more than 25 connection events.

Before you begin

You must be an Admin or Security Analyst user to perform this task.

Step 1 Choose either of the following:

- **Analysis** > **Connections** > **Events** (for connection events)
- **Analysis** > **Connections** > **Security Intelligence Events**

Note If a connection graph appears instead of a table, click **(switch workflow)** by the workflow title, and choose the predefined **Connection Events** workflow, or a custom workflow. Note that all predefined connection event workflows—including connection graphs—terminate in a table view of connections.

Step 2 You have the following choices:

- Time Range — To adjust the time range, which is useful if no events appear, see Changing the Time Window, on page 2314.
- Field Names — To learn more about the contents of the columns in the table, see Connection and Security Intelligence Event Fields, on page 2371.

  Tip In the table view of events, several fields are hidden by default, including the Category and Tag fields for each type of application, NetFlow-related fields, TLS/SSL-related fields, and others. To show a hidden field in an event view, expand the search constraints, then click the field name under **Disabled Columns**.

- Additional information — To view data in available sources external to your Firepower system, right-click an event value. The options you see depend on the data type and include public sources; other sources depend on the resources you have configured. For information, see Event Investigation Using Web-Based Resources, on page 2258
- External intelligence — To gather intelligence about an event, right-click an event value in the table and choose from a Cisco or third-party intelligence source. For example, you can get details about a suspicious IP address from Cisco Talos. The options you see depend on the data type and the integrations that are configured on your system. For more information, see Event Investigation Using Web-Based Resources, on page 2258.
- Host Profile — To view the host profile for an IP address, click **Host Profile** or, for hosts with active indications of compromise (IOC) tags, **Compromised Host** that appears next to the IP address.
- User Profile — To view user identity information, click the user icon that appears next to the **User Identity**, or for users associated with IOCs,**Red User**.
- Files and Malware —To view the files, including malware, detected or blocked in a connection, click **View Files** and proceed as described in Viewing Files and Malware Detected in a Connection, on page 2394.
- Intrusion Events — To view the intrusion events associated with a connection, as well as their priority and impact, click **Intrusion Events** in the **Intrusion Events** column and proceed as described in Viewing Intrusion Events Associated with a Connection, on page 2395.

  Tip To quickly view intrusion, file, or malware events associated with one or more connections, check the connections using the check boxes in the table, then choose the appropriate option from the **Jump to** drop-down list. Note that because they are blocked before access control rule evaluation, there can be no files or intrusions associated with connections blocked by Security Intelligence. You can only see this information for a Security Intelligence event if you configured Security Intelligence to monitor, rather than block, connections.

- Certificate — To view details about an available certificate used to encrypt a connection, click **Enabled Lock** in the **SSL Status** column.
- Constrain — To constrain the columns that appear, click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

  Tip To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, expand the search constraints, then click the column name under Disabled Columns.

- Delete Events — To delete some or all items in the current constrained view, check the check boxes next to items you want to delete and click **Delete** or click **Delete All**.
- Drill Down — See Using Drill-Down Pages, on page 2301.

  Tip To drill down using one of several Monitor rules that matched a logged connection, click an *N* **Monitor Rules** value. In the pop-up window that appears, click the Monitor rule you want to use to constrain connection events.

- Navigate This Page — See Workflow Page Traversal Tools, on page 2299.
- Navigate Between Pages — To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- Navigate Between Event Views — To navigate to other event views to view associated events, click **Jump to** and choose the event view from the drop-down list.
- Sort — To sort data in a workflow, click the column title. Click the column title again to reverse the sort order.

Viewing Files and Malware Detected in a Connection

If you associate a file policy with one or more access control rules, the system can detect files (including malware) in matching traffic. Use the Analysis > Connections menu options to see the file events, if any, associated with the connections logged by those rules. Instead of a list of files, the Firepower Management Center displays view files ( ) in the **Files** column. The number on the view files indicates the number of files (including malware files) detected or blocked in that connection.

Not all file and malware events are associated with connections. Specifically:

- Malware events detected by AMP for Endpoints ("endpoint-based malware events") are not associated with connections. Those events are imported from your AMP for Endpoints deployment.
- Many IMAP-capable email clients use a single IMAP session, which ends only when the user exits the application. Although long-running connections are logged by the system, files downloaded in the session are not associated with the connection until the session ends.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

You must be an Admin or Security Analyst user to perform this task.

Step 1 Go to **Analysis > Connections** and choose the relevant option.

Step 2 While using a connection event table, click **View Files**.
A pop-up window appears with a list of the files detected in the connection as well as their types, and if applicable, their malware dispositions.

Step 3 You have the following choices:

- View — To view a table view of file events, click a **File's View**.
- View — To view details in a table view of malware events, click a **Malware File's View**.
- Track — To track the file's transmission through your network, click a **File's Trajectory**.
- View — To view details on all of the connection's detected file or malware events detected by AMP for Networks ("network-based malware events"), click **View File Events** or **View Malware Events**.

Viewing Intrusion Events Associated with a Connection

If you associate an intrusion policy with an access control rule or default action, the system can detect exploits in matching traffic. Use the Analysis > Connections menu options to see the intrusion events, if any, associated with logged connections, as well as their priority and impact.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

You must be an Admin or Security Analyst user to perform this task.

Step 1 Go to **Analysis > Connections** and choose the relevant option.

Step 2 While using a connection event table, click **Intrusion Events** in the **Intrusion Events** column.

Step 3 In the pop-up window that appears, you have the following options:

- Click a **Listed Event's View** to view details in the packet view.
- Click **View Intrusion Events** to view details on all of the connection's associated intrusion events.

Encrypted Connection Certificate Details

You can use options under the Analysis > Connections menu to display the public key certificate (if available) used to encrypt a connection handled by the system. The certificate contains the following information.

Table 316: Encrypted Connection Certificate Details

Attribute	Description
Subject/Issuer Common Name	The host and domain name of the certificate subject or certificate issuer.
Subject/Issuer Organization	The organization of the certificate subject or certificate issuer.
Subject/Issuer Organization Unit	The organizational unit of the certificate subject or certificate issuer.
Not Valid Before/After	The dates when the certificate is valid.
Serial Number	The serial number assigned by the issuing CA.
Certificate Fingerprint	The SHA hash value used to authenticate the certificate.
Public Key Fingerprint	The SHA hash value used to authenticate the public key contained within the certificate.

Viewing the Connection Summary Page

The Connection Summary page is visible only to users who have custom roles that are restricted by searches on connection events and who have been granted explicit menu-based access to the Connection Summary page. This page provides graphs of the activity on your monitored network organized by different criteria. For example, the Connections over Time graph displays the total number of connections on your monitored network over the interval that you choose.

You can perform almost all the same actions on connection summary graphs that you can perform on connection graphs. However, because the graphs on the Connection Summary page are based on aggregated data, you cannot examine the individual connection events on which the graphs are based. In other words, you cannot drill down to a connection data table view from a connection summary graph.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Overview** > **Summary** > **Connection Summary**.

Step 2 From the **Select Device** list, choose the device whose summary you want to view, or choose **All** to view a summary of all devices.

Step 3 To manipulate and analyze the connection graphs, proceed as described in Using Connection Event Graphs, on page 2305.

Tip To detach a connection graph so you can perform further analysis without affecting the default time range, click **View**.

History for Connection and Security Intelligence Events

Feature	Version	Details
New and changed Security Group Tag fields	6.5	Changes to fields in the FMC web interface: • Changed fields: Security Group Tag is now Source SGT • New fields: Destination SGT Changes to syslog fields: • Changed fields: SecurityGroup is now SourceSecurityGroupTag • New fields: • SourceSecurityGroup • DestinationSecurityGroup • DestinationSecurityGroupTag Supported Platforms: FMC, managed devices
New syslog field: Event Priority	6.5	This field identifies connection events as High priority when they are associated with intrusion, file, malware, or Security Intelligence events.
Unique identifier for connection event in syslogs	6.4.0.4	The following syslog fields collectively uniquely identify a connection event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

CHAPTER 121

Working with Intrusion Events

The following topics describe how to work with intrusion events.

About Intrusion Events

The Firepower System can help you monitor your network for traffic that could affect the availability, integrity, and confidentiality of a host and its data. By placing managed devices on key network segments, you can examine the packets that traverse your network for malicious activity. The system has several mechanisms it uses to look for the broad range of exploits that attackers have developed.

When the system identifies a possible intrusion, it generates an *intrusion event* (sometimes called by a legacy term, "IPS event"), which is a record of the date, time, the type of exploit, and contextual information about the source of the attack and its target. For packet-based events, a copy of the packet or packets that triggered the event is also recorded. Managed devices transmit their events to the Firepower Management Center where you can view the aggregated data and gain a greater understanding of the attacks against your network assets.

You can also deploy a managed device as an inline, switched, or routed intrusion system, which allows you to configure the device to drop or replace packets that you know to be harmful.

Tools for Reviewing and Evaluating Intrusion Events

You can use the following tools to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

- An event summary page that gives you an overview of the current activity on your managed devices

- Text-based and graphical reports that you can generate for any time period you choose; you can also design your own reports and configure them to run at scheduled intervals
- An incident-handling tool that you can use to gather event data related to an attack; you can also add notes to help you track your investigation and response
- Automated alerting that you can configure for SNMP, email, and syslog
- Automated correlation policies that you can use to respond to and remediate specific intrusion events
- Predefined and custom workflows that you can use to drill down through the data to identify the events that you want to investigate further
- External tools for managing and analyzing data. You can send data to those tools using syslog or eStreamer. For more information, see Event Analysis Using External Tools, on page 2257

Additionally, you can use publicly-available information such as the predefined resources on the **Analysis > Advanced > Contextual Cross-Launch** page to learn more about malicious entities.

To search for a particular message string and retrieve documentation for the rule that generated an event, see https://www.snort.org/rule_docs/.

Viewing Intrusion Events

You view an intrusion event to determine whether there is a threat to your network security.

The initial intrusion events view differs depending on the workflow you use to access the page. You can use one of the predefined workflows, which includes one or more drill-down pages, a table view of intrusion events, and a terminating packet view, or you can create your own workflow. You can also view workflows based on custom tables, which may include intrusion events.

An event view may be slow to display if it contains a large number of IP addresses and you have enabled the **Resolve IP Addresses** event view setting.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Intrusions** > **Events**.

Step 2 You have the following choices:

- Adjust time range — Adjust the time range for the event view as described in Changing the Time Window, on page 2314.
- Change workflows — If you are using a custom workflow that does not include the table view of intrusion events, choose any of the system-provided workflows by clicking **(switch workflow)** next to the workflow title.
- Constrain — To narrow your view to the intrusion events that are important to your analysis, see Using Intrusion Event Workflows, on page 2419.
- Delete event — To delete an event from the database, click **Delete** to delete the event whose packet you are viewing or click **Delete All** to delete all the events whose packets you previously selected.
- Mark reviewed — To mark intrusion events reviewed, see Marking Intrusion Events Reviewed, on page 2414.
- View connection data —To view connection data associated with intrusion events, see Viewing Connection Data Associated with Intrusion Events, on page 2414.
- View contents — To view the contents of the columns in the table as described in Intrusion Event Fields, on page 2402.

Using the Intrusion Event Packet View, on page 2422

About Intrusion Event Fields

When the system identifies a possible intrusion, it generates an *intrusion event*, which is a record of the date, time, the type of exploit, and contextual information about the source of the attack and its target. For packet-based events, a copy of the packet or packets that triggered the event is also recorded.

You can view intrusion event data in the Firepower Management Center web interface at **Analysis > Intrusions > Events** or emit data from certain fields as syslog messages for consumption by an external tool. Syslog fields are indicated in the list below; fields without a listed syslog equivalent are not available in syslog messages.

When searching intrusion events, keep in mind that the information available for any individual event can vary depending on how, why, and when system logged the event. For example, only intrusion events triggered on decrypted traffic contain TLS/SSL information.

Note In the Firepower Management Center web interface, some fields in the table view of intrusion events are disabled by default. To enable a field for the duration of your session, expand the search constraints, then click the column name under **Disabled Columns**.

Intrusion Event Fields

Access Control Policy (Syslog: ACPolicy)

The access control policy associated with the intrusion policy where the intrusion, preprocessor, or decoder rule that generated the event is enabled.

Access Control Rule (Syslog: AccessControlRuleName)

The access control rule that invoked the intrusion policy that generated the event. `Default Action` indicates that the intrusion policy where the rule is enabled is not associated with a specific access control rule but, instead, is configured as the default action of the access control policy.

This field is empty (or, for syslog messages, omitted) if there is:

- No associated rule/default action: Intrusion inspection was associated with neither an access control rule nor the default action, for example, if the packet was examined by the intrusion policy specified to handle packets that must pass before the system can determine which rule to apply. (This policy is specified in the Advanced tab of the access control policy.)
- No associated connection event: The connection event logged for the session has been purged from the database, for example, if connection events have higher turnover than intrusion events.

Application Protocol (Syslog: ApplicationProtocol)

The application protocol, if available, which represents communications between hosts detected in the traffic that triggered the intrusion event.

Application Protocol Category and Tag

Criteria that characterize the application to help you understand the application's function.

Application Risk

The risk associated with detected applications in the traffic that triggered the intrusion event: Very High, High, Medium, Low, and Very Low. Each type of application detected in a connection has an associated risk; this field displays the highest risk of those.

Business Relevance

The business relevance associated with detected applications in the traffic that triggered the intrusion event: Very High, High, Medium, Low, and Very Low. Each type of application detected in a connection has an associated business relevance; this field displays the lowest (least relevant) of those.

Classification (Syslog: Classification)

The classification where the rule that generated the event belongs.

See a list of possible classification values in Intrusion Event Details, on page 1651.

When searching this field, enter the classification number, or all or part of the classification name or description for the rule that generated the events you want to view. You can also enter a comma-separated list of numbers, names, or descriptions. Finally, if you add a custom classification, you can also search using all or part of its name or description.

Client (Syslog: Client)

The client application, if available, which represents software running on the monitored host detected in the traffic that triggered the intrusion event.

Client Category and Tag

Criteria that characterize the application to help you understand the application's function.

Connection Counter (Syslog Only)

A counter that distinguishes one connection from another simultaneous connection. This field has no significance on its own.

The following fields collectively uniquely identify the connection event associated with a particular intrusion event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Connection Instance ID (Syslog Only)

The Snort instance that processed the connection event. This field has no significance on its own.

The following fields collectively uniquely identify the connection event associated with a particular intrusion event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

CVE ID

This field is a search field only.

Search by the identification number associated with the vulnerability in MITRE's Common Vulnerabilities and Exposures (CVE) database (https://cve.mitre.org/).

Destination Continent

The continent of the receiving host involved in the intrusion event.

Destination Country

The country of the receiving host involved in the intrusion event.

Destination IP (Syslog: DstIP)

The IP address used by the receiving host involved in the intrusion event.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

Destination Port / ICMP Code (Syslog: DstPort, ICMPCode)

The port number for the host receiving the traffic. For ICMP traffic, where there is no port number, this field displays the ICMP code.

Destination User

The username associated with the Responder IP of the connection event. This host may or may not be the host receiving the exploit. This value is typically known only for users on your network.

.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

Device

The managed device where the access control policy was deployed.

DeviceUUID (Syslog Only)

The unique identifier of the Firepower device that generated an event.

The following fields collectively uniquely identify the connection event associated with a particular intrusion event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Domain

The domain of the device that detected the intrusion. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Egress Interface (Syslog: EgressInterface)

The egress interface of the packet that triggered the event. This interface column is not populated for a passive interface.

Egress Security Zone (Syslog: EgressZone)

The egress security zone of the packet that triggered the event. This security zone field is not populated in a passive deployment.

Email Attachments

The MIME attachment file name that was extracted from the MIME Content-Disposition header. To display attachment file names, you must enable the SMTP preprocessor **Log MIME Attachment Names** option. Multiple attachment file names are supported.

Email Headers

This field is a search field only.

The data that was extracted from the email header.

To associate email headers with intrusion events for SMTP traffic, you must enable the SMTP preprocessor **Log Headers** option.

Email Recipient

The address of the email recipient that was extracted from the SMTP RCPT TO command. To display a value for this field, you must enable the SMTP preprocessor **Log To Addresses** option. Multiple recipient addresses are supported.

Email Sender

The address of the email sender that was extracted from the SMTP MAIL FROM command. To display a value for this field, you must enable the SMTP preprocessor **Log From Address** option. Multiple sender addresses are supported.

First Packet Time (Syslog Only)

The time the system encountered the first packet.

The following fields collectively uniquely identify the connection event associated with a particular intrusion event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Generator

The component that generated the event.

See also information about the following intrusion event fields: GID, Message, and Snort ID.

GID (Syslog Only)

Generator ID; the ID of the component that generated the event.

See also information about the following intrusion event fields: Generator, Message, and Snort ID.

HTTP Hostname

The host name, if present, that was extracted from the HTTP request Host header. Note that request packets do not always include the host name.

To associate host names with intrusion events for HTTP client traffic, you must enable the HTTP Inspect preprocessor **Log Hostname** option.

In table views, this column displays the first fifty characters of the extracted host name. You can hover your pointer over the displayed portion of an abbreviated host name to display the complete name, up to 256 bytes. You can also display the complete host name, up to 256 bytes, in the packet view.

HTTP Response Code (Syslog: HTTPResponse)

The HTTP status code sent in response to a client's HTTP request over the connection that triggered the event.

HTTP URI

The raw URI, if present, associated with the HTTP request packet that triggered the intrusion event. Note that request packets do not always include a URI.

To associate URIs with intrusion events for HTTP traffic, you must enable the HTTP Inspect preprocessor **Log URI** option.

To see the associated HTTP URI in intrusion events triggered by HTTP responses, you should configure HTTP server ports in the **Perform Stream Reassembly on Both Ports** option; note, however, that this increases resource demands for traffic reassembly.

This column displays the first fifty characters of the extracted URI. You can hover your pointer over the displayed portion of an abbreviated URI to display the complete URI, up to 2048 bytes. You can also display the complete URI, up to 2048 bytes, in the packet view.

Impact

The impact level in this field indicates the correlation between intrusion data, network discovery data, and vulnerability information.

When searching this field, do not specify impact icon colors or partial strings. For example, do not use **`blue`**, **`level 1`**, or **`0`**. Valid case-insensitive values are:

- Impact 0, Impact Level 0
- Impact 1, Impact Level 1
- Impact 2, Impact Level 2
- Impact 3, Impact Level 3
- Impact 4, Impact Level 4

Because no operating system information is available for hosts added to the network map from NetFlow data, the system cannot assign Vulnerable (impact level 1: red) impact levels for intrusion events involving those hosts. In such cases, use the host input feature to manually set the operating system identity for the hosts.

Ingress Interface (Syslog: IngressInterface)

The ingress interface of the packet that triggered the event. Only this interface column is populated for a passive interface.

Ingress Security Zone (Syslog: IngressZone)

The ingress security zone or tunnel zone of the packet that triggered the event. Only this security zone field is populated in a passive deployment.

Inline Result (Syslog: InlineResult)

In workflow and table views, this field displays one of the following:

Table 317: Inline Result Field Contents in Workflow and Table Views

This Icon	Indicates
A black down arrow	The system dropped the packet that triggered the rule.
A gray down arrow	IPS would have dropped the packet if you enabled the **Drop when Inline** intrusion policy option (in an inline deployment), or if a Drop and Generate rule generated the event while the system was pruning.

This Icon	Indicates
No icon (blank)	The triggered rule was not set to Drop and Generate Events

In a passive deployment, the system does not drop packets, including when an inline interface is in tap mode, regardless of the rule state or the inline drop behavior of the intrusion policy.

When searching this field, enter either of the following:

- **`dropped`** to specify whether the packet is dropped in an inline deployment.
- **`would have dropped`** to specify whether the packet would have dropped if the intrusion policy had been set to drop packets in an inline deployment.

Intrusion Policy (Syslog: IntrusionPolicy)

The intrusion policy where the intrusion, preprocessor, or decoder rule that generated the event was enabled. You can choose an intrusion policy as the default action for an access control policy, or you can associate an intrusion policy with an access control rule.

IOC (Syslog: NumIOC)

Whether the traffic that triggered the intrusion event also triggered an indication of compromise (IOC) for a host involved in the connection.

When searching this field, specify **`triggered`** or **`n/a`**.

Message (Syslog: Message)

The explanatory text for the event. For rule-based intrusion events, the event message is pulled from the rule. For decoder- and preprocessor-based events, the event message is hard coded.

The Generator and Snort IDs (GID and SID) and the SID version (Revision) are appended in parentheses to the end of each message in the format of numbers separated by colons (GID:SID:version). For example **`(1:36330:2)`**.

MPLS Label (Syslog: MPLS_Label)

The Multiprotocol Label Switching label associated with the packet that triggered the intrusion event.

Network Analysis Policy (Syslog: NAPPolicy)

The network analysis policy, if any, associated with the generation of the event.

This field displays the first fifty characters of the extracted URI. You can hover your pointer over the displayed portion of an abbreviated URI to display the complete URI, up to 2048 bytes. You can also display the complete URI, up to 2048 bytes, in the packet view.

Original Client IP

The original client IP address that was extracted from an X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header.

To display a value for this field, you must enable the HTTP preprocessor **Extract Original Client IP Address** option in the network analysis policy. Optionally, in the same area of the network analysis policy, you can

also specify up to six custom client IP headers, as well as set the priority order in which the system selects the value for the Original Client IP event field.

Priority (Syslog: Priority)

The event priority as determined by the Cisco Talos Intelligence Group (Talos). The priority corresponds to either the value of the `priority` keyword or the value for the `classtype` keyword. For other intrusion events, the priority is determined by the decoder or preprocessor. Valid values are high, medium, and low.

Protocol (Syslog: Protocol)

In the Firepower Management Center web interface, this field is a search field only.

The name or number of the transport protocol used in the connection as listed in http://www.iana.org/assignments/protocol-numbers. This is the protocol associated with the source and destination port/ICMP column.

Reviewed By

The name of the user who reviewed the event. When searching this field, you can enter **`unreviewed`** to search for events that have not been reviewed.

Revision (Syslog Only)

The version of the signature that was used to generate the event.

See also information about the following intrusion event fields: Generator, GID, Message, SID, and Snort ID.

Security Context (Syslog: Context)

The metadata identifying the virtual firewall group through which the traffic passed. The system only populates this field for ASA FirePOWER in multiple context mode.

SID (Syslog Only)

The signature ID (also known as the Snort ID) of the rule that generated the event.

See also information about the following intrusion event fields: Generator, GID, Message, Revision, and Snort ID.

Snort ID

This field is a search field only.

(For the syslog field, see SID.)

When performing your search: Specify the Snort ID (SID) of the rule that generated the event or, optionally, specify the combination Generator ID (GID) and SID of the rule, where the GID and SID are separated with a colon (:) in the format GID:SID. You can specify any of the values in the following table:

Table 318: Snort ID Search Values

Value	Example
a single SID	10000

Value	Example
a SID range	10000-11000
greater than a SID	>10000
greater than or equal to a SID	>=10000
less than a SID	<10000
less than or equal to a SID	<=10000
a comma-separated list of SIDs	10000,11000,12000
a single GID:SID combination	1:10000
a comma-separated list of GID:SID combinations	1:10000,1:11000,1:12000
a comma-separated list of SIDs and GID:SID combinations	10000,1:11000,12000

The SID of the events you are viewing is listed in the Message column. For more information, see the description in this section for the Message field.

Source Continent

The continent of the sending host involved in the intrusion event.

Source Country

The country of the sending host involved in the intrusion event.

Source IP (Syslog: SrcIP)

The IP address used by the sending host involved in the intrusion event.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

Source Port / ICMP Type (Syslog: SrcPort, ICMPType)

The port number on the sending host. For ICMP traffic, where there is no port number, this field displays the ICMP type.

Source User (Syslog: User)

The username associated with the IP address of the host that initiated the connection, which may or may not be the source host of the exploit. This user value is typically known only for users on your network.

If applicable, the username is preceded by `<realm>\`.

SSL Actual Action (Syslog: SSLActualAction)

In the Firepower Management Center web interface, this field is a search field only.

The action the system applied to encrypted traffic:

Block/Block with reset

Represents blocked encrypted connections.

Decrypt (Resign)

Represents an outgoing connection decrypted using a re-signed server certificate.

Decrypt (Replace Key)

Represents an outgoing connection decrypted using a self-signed server certificate with a substituted public key.

Decrypt (Known Key)

Represents an incoming connection decrypted using a known private key.

Default Action

Indicates the connection was handled by the default action.

Do not Decrypt

Represents a connection the system did not decrypt.

Field values are displayed in the **SSL Status** field on the search workflow pages.

SSL Certificate Information

This field is a search field only.

The information stored on the public key certificate used to encrypt traffic, including:

- Subject/Issuer Common Name
- Subject/Issuer Organization
- Subject/Issuer Organization Unit
- Not Valid Before/After
- Serial Number
- Certificate Fingerprint
- Public Key Fingerprint

SSL Failure Reason

This field is a search field only.

The reason the system failed to decrypt encrypted traffic:

- Unknown
- No Match
- Success
- Uncached Session
- Unknown Cipher Suite

- Unsupported Cipher Suite
- Unsupported SSL Version
- SSL Compression Used
- Session Undecryptable in Passive Mode
- Handshake Error
- Decryption Error
- Pending Server Name Category Lookup
- Pending Common Name Category Lookup
- Internal Error
- Network Parameters Unavailable
- Invalid Server Certificate Handle
- Server Certificate Fingerprint Unavailable
- Cannot Cache Subject DN
- Cannot Cache Issuer DN
- Unknown SSL Version
- External Certificate List Unavailable
- External Certificate Fingerprint Unavailable
- Internal Certificate List Invalid
- Internal Certificate List Unavailable
- Internal Certificate Unavailable
- Internal Certificate Fingerprint Unavailable
- Server Certificate Validation Unavailable
- Server Certificate Validation Failure
- Invalid Action

Field values are displayed in the **SSL Status** field on the search workflow pages.

SSL Status

The action associated with the **SSL Actual Action** (SSL rule, default action, or undecryptable traffic action) that logged the encrypted connection.

If the system fails to decrypt an encrypted connection, it displays the **SSL Actual Action** (undecryptable traffic action) taken, as well as the **SSL Failure Reason**. For example, if the system detects traffic encrypted with an unknown cipher suite and allows it without further inspection, this field displays `Do Not Decrypt (Unknown Cipher Suite)`.

Click the **Lock icon** to view certificate details.

When searching this field, enter one or more of the **SSL Actual Action** and **SSL Failure Reason** values to view encrypted traffic the system handled or failed to decrypt.

SSL Subject/Issuer Country

This field is a search field only.

A two-character ISO 3166-1 alpha-2 country code for the subject or issuer country associated with the encryption certificate.

Time

The date and time of the event. This field is not searchable.

VLAN ID (Syslog: VLAN_ID)

The innermost VLAN ID associated with the packet that triggered the intrusion event.

Web Application (Syslog: WebApplication)

The web application, which represents the content or requested URL for HTTP traffic detected in the traffic that triggered the intrusion event.

If the system detects an application protocol of HTTP but cannot detect a specific web application, the system supplies a generic web browsing designation instead.

Web Application Category and Tag

Criteria that characterize the application to help you understand the application's function.

Related Topics

Event Searches, on page 2323

Intrusion Event Impact Levels

To help you evaluate the impact an event has on your network, the Firepower Management Center displays an impact level in the table view of intrusion events. For each event, the system adds an impact level icon whose color indicates the correlation between intrusion data, network discovery data, and vulnerability information.

Note Because no operating system information is available for hosts added to the network map from NetFlow data, the system cannot assign Vulnerable (impact level 1: red) impact levels for intrusion events involving those hosts. In such cases, use the host input feature to manually set the operating system identity for the hosts.

The following table describes the possible values for the impact levels.

Table 319: Impact Levels

Impact Level	Vulnerability	Color	Description
Unknown (0)	Unknown	gray	Neither the source nor the destination host is on a network that is monitored by network discovery.
Vulnerable (1)	Vulnerable	red	Either: • the source or the destination host is in the network map, and a vulnerability is mapped to the host • the source or destination host is potentially compromised by a virus, trojan, or other piece of malicious software
Potentially Vulnerable (2)	Potentially Vulnerable	orange	Either the source or the destination host is in the network map and one of the following is true: • for port-oriented traffic, the port is running a server application protocol • for non-port-oriented traffic, the host uses the protocol
Currently Not Vulnerable (3)	Currently Not Vulnerable	yellow	Either the source or the destination host is in the network map and one of the following is true: • for port-oriented traffic (for example, TCP or UDP), the port is not open • for non-port-oriented traffic (for example, ICMP), the host does not use the protocol
Unknown Target (4)	Unknown Target	blue	Either the source or destination host is on a monitored network, but there is no entry for the host in the network map.

Viewing Connection Data Associated with Intrusion Events

The system can log the connections where intrusion events are detected. Although this logging is automatic for intrusion policies associated with access control rules, you must manually enable connection logging to see associated connection data for the default action.

Viewing associated data is most useful when navigating between table views of events.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Intrusions** > **Events**.

Step 2 Choose the intrusion events using the check boxes in the table, then choose **Connections** from the **Jump to** drop-down list.

Tip You can view the intrusion events associated with particular connections in a similar way. For more information, see Inter-Workflow Navigation, on page 2319.

Related Topics

Logging for Allowed Connections, on page 2358
Using Intrusion Event Workflows, on page 2419
Using Connection and Security Intelligence Event Tables, on page 2392

Marking Intrusion Events Reviewed

If you are confident that an intrusion event is not malicious, you can mark the event reviewed.

If you have examined an intrusion event and are confident that the event does not represent a threat to your network security (for example, because you know that none of the hosts on your network are vulnerable to the detected exploit), you can mark the event reviewed. Reviewed events are stored in the event database and are included in the event summary statistics, but no longer appear in the default intrusion event pages. Your name appears as the reviewer.

In a multidomain deployment, if you mark an event reviewed, the system marks it reviewed in all domains that can view that event.

If you perform a backup and then delete reviewed intrusion events, restoring your backup restores the deleted intrusion events but does not restore their reviewed status. You view those restored intrusion events under **Intrusion Events**, not under **Reviewed Events**.

On a page that displays intrusion events, you have two options:

- To mark one or more intrusion events from the list of events, check the check boxes next to the events and click **Review**.
- To mark all intrusion events from the list of events, click **Review All**.

Related Topics

Using Intrusion Event Workflows, on page 2419

Viewing Previously Reviewed Intrusion Events

In a multidomain deployment, if you mark an event reviewed, the system marks it reviewed in all domains that can view that event.

Step 1 Choose **Analysis** > **Intrusions** > **Reviewed Events**.

Step 2 You have the following choices:

- Adjust the time range as described in Changing the Time Window, on page 2314.
- If you are using a custom workflow that does not include the table view of intrusion events, choose any of the system-provided workflows by clicking **(switch workflow)** next to the workflow title.
- To learn more about the events that appear, see Intrusion Event Fields, on page 2402.

Related Topics

Using Intrusion Event Workflows, on page 2419

Marking Reviewed Intrusion Events Unreviewed

You can return a reviewed event to the default intrusion events view by marking the event unreviewed.

In a multidomain deployment, if you mark an event reviewed, the system marks it reviewed in all domains that can view that event.

On a page that displays reviewed events, you have two choices:

- To remove individual intrusion events from the list of reviewed events, check the check boxes next to specific events and click **Unreview**.
- To remove all intrusion events from the list of reviewed events, click **Unreview All**.

Preprocessor Events

Preprocessors provide two functions: performing the specified action on the packet (for example, decoding and normalizing HTTP traffic) and reporting the execution of specified preprocessor options by generating an event whenever a packet triggers that preprocessor option and the associated preprocessor rule is enabled. For example, you can enable the `Double Encoding` HTTP Inspect option and the associated preprocessor rule with the HTTP Inspect Generator (GID) 119 and the Snort ID (SID) 2 to generate an event when the preprocessor encounters IIS double-encoded traffic.

Generating events to report the execution of preprocessors helps you detect anomalous protocol exploits. For example, attackers can craft overlapping IP fragments to cause a DoS attack on a host. The IP defragmentation preprocessor can detect this type of attack and generate an intrusion event for it.

Preprocessor events differ from rule events in that the packet display does not include a detailed rule description for the event. Instead, the packet display shows the event message, the GID, SID, the packet header data, and the packet payload. This allows you to analyze the packet's header information, determine if its header options are being used and if they can exploit your system, and inspect the packet payload. After the preprocessors analyze each packet, the rules engine executes appropriate rules against it (if the preprocessor was able to defragment it and establish it as part of a valid session) to further analyze potential content-level threats and report on them.

Preprocessor Generator IDs

Each preprocessor has its own Generator ID number, or GID, that indicates which preprocessor was triggered by the packet. Some of the preprocessors also have related SIDs, which are ID numbers that classify potential attacks. This helps you analyze events more effectively by categorizing the type of event much the way a rule's Snort ID (SID) can offer context for packets triggering rules. You can list preprocessor rules by preprocessor in the Preprocessors filter group on the intrusion policy Rules page; you can also list preprocessor rules in the preprocessor and packet decoder sub-groupings in the Category filter group.

Note Events generated by standard text rules have a generator ID of 1 (Global domain or legacy GID) or 1000 - 2000 (descendant domains). For shared object rules, the events have a generator ID of 3. For both, the event's SID indicates which specific rule triggered.

The following table describes the types of events that generate each GID.

Table 320: Generator IDs

ID	Component	Description
1	Standard Text Rule	The event was generated when the packet triggered a standard text rule (Global domain or legacy GID).
2	Tagged Packets	The event was generated by the Tag generator, which generates packets from a tagged session. This occurs when the `tag` rule option is used.
3	Shared Object Rule	The event was generated when the packet triggered a shared object rule.
102	HTTP Decoder	The decoder engine decoded HTTP data within the packet.
105	Back Orifice Detector	The Back Orifice Detector identified a Back Orifice attack associated with the packet.
106	RPC Decoder	The RPC decoder decoded the packet.
116	Packet Decoder	The event was generated by the packet decoder.

ID	Component	Description
119, 120	HTTP Inspect Preprocessor	The event was generated by the HTTP Inspect preprocessor. GID 120 rules relate to server-specific HTTP traffic.
122	Portscan Detector	The event was generated by the portscan flow detector.
123	IP Defragmentor	The event was generated when a fragmented IP datagram could not be properly reassembled.
124	SMTP Decoder	The event was generated when the SMTP preprocessor detected an exploit against an SMTP verb.
125	FTP Decoder	The event was generated when the FTP/Telnet decoder detected an exploit within FTP traffic.
126	Telnet Decoder	The event was generated when the FTP/Telnet decoder detected an exploit within telnet traffic.
128	SSH Preprocessor	The event was generated when the SSH preprocessor detected an exploit within SSH traffic.
129	Stream Preprocessor	The event was generated during stream preprocessing by the stream preprocessor.
131	DNS Preprocessor	The event was generated by the DNS preprocessor.
133	DCE/RPC Preprocessor	The event was generated by the DCE/RPC preprocessor.
134	Rule Latency Packet Latency	The event was generated when rule latency suspended (134:1) or re-enabled (134:2) a group of intrusion rules, or when the system stopped inspecting a packet because the packet latency threshold was exceeded (134:3).
135	Rate-Based Attack Detector	The event was generated when a rate-based attack detector identified excessive connections to hosts on the network.
137	SSL Preprocessor	The event was generated by the TLS/SSL preprocessor.
138, 139	Sensitive Data Preprocessor	The event was generated by the sensitive data preprocessor.

ID	Component	Description
140	SIP Preprocessor	The event was generated by the SIP preprocessor.
141	IMAP Preprocessor	The event was generated by the IMAP preprocessor.
142	POP Preprocessor	The event was generated by the POP preprocessor.
143	GTP Preprocessor	The event was generated by the GTP preprocessor.
144	Modbus Preprocessor	The event was generated by the Modbus SCADA preprocessor.
145	DNP3 Preprocessor	The event was generated by the DNP3 SCADA preprocessor.
148	CIP Preprocessor	The event was generated by the CIP SCADA preprocessor.
1000 - 2000	Standard Text Rule	The event was generated when the packet triggered a standard text rule (descendant domains).

Intrusion Event Workflow Pages

The preprocessor, decoder, and intrusion rules that are enabled in the current intrusion policy generate intrusion events whenever the traffic that you monitor violates the policy.

The Firepower System provides a set of predefined workflows, populated with event data, that you can use to view and analyze intrusion events. Each of these workflows steps you through a series of pages to help you pinpoint the intrusion events that you want to evaluate.

The predefined intrusion event workflows contain three different types of pages, or event views:

- one or more drill-down pages
- the table view of intrusion events
- a packet view

Drill-down pages generally include two or more columns in a table (and, for some drill-down views, more than one table) that allow you to view one specific type of information.

When you “drill down” to find more information for one or more destination ports, you automatically select those events and the next page in the workflow appears. In this way, drill-down tables help you reduce the number of events you are analyzing at one time.

The initial *table view* of intrusion events lists each intrusion event in its own row. The columns in the table list information such as the time, the source IP address and port, the destination IP address and port, the event priority, the event message, and more.

When you select events on a table view, instead of selecting events and displaying the next page in the workflow, you add to what are called *constraints*. Constraints are limits that you impose on the types of events that you want to analyze.

For example, if you click **Close** ( ) in any column and clear **Time** from the drop-down list, you can remove Time as one of the columns. To narrow the list of events in your analysis, you can click the link for a value in one of the rows in the table view. For example, to limit your analysis to the events generated from one of the source IP addresses (presumably, a potential attacker), click the IP address in the **Source IP Address** column.

If you select one or more rows in a table view and then click **View**, the packet view appears. A *packet view* provides information about the packet that triggered the rule or the preprocessor that generated the event. Each section of the packet view contains information about a specific layer in the packet. You can expand collapsed sections to see more information.

Note Because each portscan event is triggered by multiple packets, portscan events use a special version of the packet view.

If the predefined workflows do not meet your specific needs, you can create custom workflows that display only the information you are interested in. Custom intrusion event workflows can include drill-down pages, a table view of events, or both; the system automatically includes a packet view as the last page. You can easily switch between the predefined workflows and your own custom workflows depending on how you want to investigate events.

Using Intrusion Event Workflows

The drill-down views and table view of events share some common features that you can use to narrow a list of events and then concentrate your analysis on a group of related events.

To avoid displaying the same intrusion events on different workflow pages, the time range pauses when you click a link at the bottom of the page to display another page of events, and resumes when you click to take any other action on the subsequent page.

Tip At any point in the process, you can save the constraints as a set of search criteria. For example, if you find that over the course of a few days your network is being probed by an attacker from a single IP address, you can save your constraints during your investigation and then use them again later. You cannot, however, save compound constraints as a set of search criteria.

Step 1 Access an intrusion event workflow using **Analysis** > **Intrusions** > **Events**.

Step 2 Optionally, constrain the number of intrusion events that appear on the event views as described in Intrusion Event Drill-Down Page Constraints, on page 2421 or Intrusion Event Table View Constraints, on page 2422.

Step 3 You have the following choices:

- To learn more about the columns that appear, see Intrusion Event Fields, on page 2402.
- To view a host's profile, click **Host Profile** that appears next to the host IP address.
- To view geolocation details, click flag that appears in the Source Country or Destination Country columns.
- To view data in available sources external to your Firepower system, right-click an event value. The options you see depend on the data type and include public sources; other sources depend on the resources you have configured. For information, see Event Investigation Using Web-Based Resources, on page 2258
- To gather general intelligence about an event, right-click an event value in the table and choose from a Cisco or third-party intelligence source. For example, you can get details about a suspicious IP address from Cisco Talos. The options you see depend on the data type and the integrations that are configured on your system. For more information, see Event Investigation Using Web-Based Resources, on page 2258.
- To modify the time and date range for displayed events, see Changing the Time Window, on page 2314.

  Tip If no intrusion events appear on the event views, adjusting the specified time range might return results. If you specified an older time range, events in that time range might have been deleted. Adjusting the rule thresholding configuration might generate events.

  Note Events generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.

- To sort events on the current workflow page or navigate within the current workflow page, see Using Workflows, on page 2294.
- To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- To add events to the clipboard so you can transfer them to an incident at a later time, click **Copy** or **Copy All**.
- To delete events from the event database, check the check boxes next to events you want to delete, then click **Delete**, or click **Delete All**.
- To mark events reviewed to remove them from intrusion event pages, but not the event database, see Marking Intrusion Events Reviewed, on page 2414.
- To download a local copy of the packet (a packet capture file in libpcap format) that triggered each selected event, check the check boxes next to events triggered by the packets you want to download, then click **Download Packets**, or click **Download All Packets**. Captured packets are saved in libpcap format. This format is used by several popular protocol analyzers.
- To navigate to other event views to view associated events, see Inter-Workflow Navigation, on page 2319.
- To temporarily use a different workflow, click **(switch workflow)**.
- To bookmark the current page so that you can quickly return to it, click **Bookmark This Page**.
- To view the Intrusion Events section of the Summary Dashboard, click **Dashboards**.
- To navigate to the bookmark management page, click **View Bookmarks**.

- To generate a report based on the data in the current view, see Creating a Report Template from an Event View, on page 2174.

Intrusion Event Drill-Down Page Constraints

The following table describes how to use the drill-down pages.

Table 321: Constraining Events on Drill-Down Pages

To...	You can...
drill down to the next workflow page constraining on a specific value	click the value. For example, on the Destination Port workflow, to constrain the events to those with a destination of port 80, click **80/tcp** in the **DST Port/ICMP Code** column. The next page of the workflow, Events, appears and contains only port 80/tcp events.
drill down to the next workflow page constraining on selected events	select the check boxes next to the events you want to view on the next workflow page, then click **View**. For example, on the Destination Port workflow, to constrain the events to those with destination ports 20/tcp and 21/tcp, select the check boxes next to the rows for those ports and click **View**. The next page of the workflow, Events, appears and contains only port 20/tcp and 21/tcp events. Note that if you constrain on multiple rows and the table has more than one column (not including a Count column), you build what is called a compound constraint. Compound constraints ensure that you do not include more events in your constraint than you mean to. For example, if you use the Event and Destination workflow, each row that you select on the first drill-down page creates a compound constraint. If you pick event 1:100 with a destination IP address of 10.10.10.100 and you also pick event 1:200 with a destination IP address of 192.168.10.100, the compound constraint ensures that you do not also select events with 1:100 as the event type and 192.168.10.100 as the destination IP address or events with 1:200 as the event type and 10.10.10.100 as the destination IP address.
drill down to the next workflow page keeping the current constraints	click **View All**.

Intrusion Event Table View Constraints

The following table describes how to use the table view.

Table 322: Constraining Events on the Table View of Events

To...	You can...
constrain the view to events with a single attribute	click the attribute. For example, to constrain the view to events with a destination of port 80, click **80/tcp** in the **DST Port/ICMP Code** column.
remove a column from the table	click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**. If you want to hide or show other columns, select or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, click the **expand arrow** to expand the search constraints, then click the column name under **Disabled Columns**.
view the packets associated with one or more events	either: • click the **down arrow** next to the event whose packets you want to view. • select one or more events whose packets you want to view, and, at the bottom of the page, click **View.** • at the bottom of the page, click **View All** to view the packets for all events that match the current constraints.

Using the Intrusion Event Packet View

A packet view provides information about the packet that triggered the rule that generated an intrusion event.

Tip The packet view on a Firepower Management Center does not contain packet information when the **Transfer Packet** option is disabled for the device detecting the event.

The packet view indicates why a specific packet was captured by providing information about the intrusion event that the packet triggered, including the event's time stamp, message, classification, priority, and, if the event was generated by a standard text rule, the rule that generated the event. The packet view also provides general information about the packet, such as its size.

In addition, the packet view has a section that describes each layer in the packet: data link, network, and transport, as well as a section that describes the bytes that comprise the packet. If the system decrypted the packet, you can view the decrypted bytes. You can expand collapsed sections to display detailed information.

Note Because each portscan event is triggered by multiple packets, portscan events use a special version of the packet view.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 On the table view of intrusion events, choose packets to view as described in Intrusion Event Table View Constraints, on page 2422.

Step 2 Optionally, if you chose more than one event, you can page through the packets in the packet view by using the page numbers at the bottom of the page.

Step 3 You also have the following options:

- Adjust — To modify the date and time range in the packet views, see Changing the Time Window, on page 2314.
- Clipboard — To add an event to the clipboard so you can transfer it to the incidents at a later time, click **Copy** to copy the event whose packet you are viewing or click **Copy All** to copy all the events whose packets you previously selected.
- Configure — To configure the intrusion rule that triggered the event, click the arrow next to Actions and continue as described in Configuring Intrusion Rules within the Packet View, on page 2426.
- Delete — To delete an event from the database, click **Delete** to delete the event whose packet you are viewing or click **Delete All** to delete all the events whose packets you previously selected.
- Download — To download a local copy of the packet (a packet capture file in libpcap format) that triggered the event, click **Download Packet** to save a copy of the captured packet for the event you are viewing or click **Download All Packets** to save copies of the captured packets for all the events whose packets you previously selected. The captured packet is saved in libpcap format. This format is used by several popular protocol analyzers.

  Note You cannot download a portscan packet because single portscan events are based on multiple packets; however, the portscan view provides all usable packet information. You must have at least 15% available disk space in order to download.

- Mark reviewed — To mark an event reviewed to remove it from event views, but not the event database, click **Review** to mark the event whose packet you are viewing or click **Review All** to mark all the events whose packets you previously selected. For more information, see Marking Intrusion Events Reviewed, on page 2414.
- View additional information — To expand or collapse a page section, click the arrow next to the section. For details, see Event Information Fields, on page 2423, Frame Information Fields, on page 2429, and Data Link Layer Information Fields, on page 2430.
- View network layer information — See Viewing Network Layer Information, on page 2431.
- View packet byte information — See Viewing Packet Byte Information, on page 2436.
- View transport layer information — See Viewing Transport Layer Information, on page 2433

Portscan Detection, on page 1893
The Intrusion Events Clipboard, on page 2436

Event Information Fields

On the packet view, you can view information about the packet in the Event Information section.

Event

The event message. For rule-based events, this corresponds to the rule message. For other events, this is determined by the decoder or preprocessor.

The ID for the event is appended to the message in the format (GID:SID:Rev). GID is the generator ID of the rules engine, the decoder, or the preprocessor that generated the event. SID is the identifier for the rule, decoder message, or preprocessor message. Rev is the revision number of the rule.

Timestamp

The time that the packet was captured, in UTC time zone.

Classification

The event classification. For rule-based events, this corresponds to the rule classification. For other events, this is determined by the decoder or preprocessor.

Priority

The event priority. For rule-based events, this corresponds to either the value of the `priority` keyword or the value for the `classtype` keyword. For other events, this is determined by the decoder or preprocessor.

Ingress Security Zone

The ingress security zone of the packet that triggered the event. Only this security zone field is populated in a passive deployment.

Egress Security Zone

The egress security zone of the packet that triggered the event. This field is not populated in a passive deployments

Domain

The domain where the managed device belongs. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Device

The managed device where the access control policy was deployed.

Security Context

The metadata identifying the virtual firewall group through which the traffic passed. Note that the system only populates this field for ASA FirePOWER in multiple context mode.

Ingress Interface

The ingress interface of the packet that triggered the event. Only this interface column is populated for a passive interface.

Egress Interface

For an inline set, the egress interface of the packet that triggered the event.

Source/Destination IP

The host IP address or domain name where the packet that triggered the event (source) originated, or the target (destination) host of the traffic that triggered the event.

Source Port/ICMP Type

Source port of the packet that triggered the event. For ICMP traffic, where there is no port number, the system displays the ICMP type.

Destination Port/ICMP Code

The port number for the host receiving the traffic. For ICMP traffic, where there is no port number, the system displays the ICMP code.

Email Headers

The data that was extracted from the email header. Note that email headers do not appear in the table view of intrusion events, but you can use email header data as a search criterion.

To associate email headers with intrusion events for SMTP traffic, you must enable the SMTP preprocessor **Log Headers** option. For rule-based events, this row appears when email data is extracted.

HTTP Hostname

The host name, if present, extracted from the HTTP request Host header. This row displays the complete host name, up to 256 bytes. You can expand the complete host name if it is longer than a single row.

To display host names, you must enable the HTTP Inspect preprocessor **Log Hostname** option.

Note that HTTP request packets do not always include a host name. For rule-based events, this row appears when the packet contains the HTTP host name or the HTTP URI.

HTTP URI

The raw URI, if present, associated with the HTTP request packet that triggered the intrusion event. This row displays the complete URI, up to 2048 bytes. You can expand the complete URI if it is longer than a single row.

To display the URI, you must enable the HTTP Inspect preprocessor **Log URI** option.

Note that HTTP request packets do not always include a URI. For rule-based events, this row appears when the packet contains the HTTP host name or the HTTP URI.

To see the associated HTTP URI in intrusion events triggered by HTTP responses, you should configure HTTP server ports in the **Perform Stream Reassembly on Both Ports** option; note, however, that this increases resource demands for traffic reassembly.

Intrusion Policy

The intrusion policy, if present, where the intrusion, preprocessor, or decoder rule that generated the intrusion event was enabled. You can choose an intrusion policy as the default action for an access control policy or associate an intrusion policy with an access control rule.

Access Control Policy

The access control policy that includes the intrusion policy where the intrusion, preprocessor, or decoder rule that generated the event is enabled.

Access Control Rule

The access control rule associated with an intrusion rule that generated the event. Default Action indicates that the intrusion policy where the rule is enabled is not associated with an access control rule but, instead, is configured as the default action of the access control policy.

Rule

For standard text rule events, the rule that generated the event.

Note that if the event is based on a shared object rule, a decoder, or a preprocessor, the rule is not available.

Because rule data may contain sensitive information about your network, administrators may toggle users' ability to view rule information in the packet view with the View Local Rules permission in the user role editor.

Actions

For standard text and custom rule events, expand **Actions** to take any of the following actions on the rule that triggered the event:

- edit the rule
- view documentation for the revision of the rule; for standard text rules only, after clicking **View Documentation** under Actions, you can click **Rule Documentation** in the documentation pop-up window to view more-specific rule details.
- add a comment to the rule
- change the state of the rule
- set a threshold for the rule
- suppress the rule

Note that if the event is based on a shared object rule, a decoder, or a preprocessor, the rule is not available.

Configuring Intrusion Rules within the Packet View

Within the packet view of an intrusion event, you can take several actions on the rule that triggered the event. Note that if the event is based on a shared object rule, a decoder, or a preprocessor, the rule is not available.

Step 1 Within the packet view of an intrusion event that was generated by an intrusion rule, expand **Actions** in the Event Information section.

Step 2 You have the following choices:

- Comment — For standard text rule events, click **Rule Comment** to add a text comment to the rule that generated the event. This allows you to provide additional context and information about the rule and the exploit or policy violation it identifies. You can also add and view rule comments in the intrusion rules editor.
- Disable — Click **Disable this rule...** to disable the rule.

If this event is generated by a standard text rule, you can disable the rule, if necessary. You can set the rule in all policies that you can edit locally. Alternately, you can set the rule only in the current policy (that is, the policy that generated the event) if you can edit the current policy locally.

Note that the current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by the system.

Note You **cannot** disable shared object rules from the packet view, nor can you disable rules in the default policies.

- Drop packets — Click **Set this rule to drop the triggering packet...** to set the rule to drop packets that trigger it.

  If your managed device is deployed inline on your network, you can set the rule that triggered the event to drop packets that trigger the rule in all policies that you can edit locally. Alternately, you can set the rule only in the current policy (that is, the policy that generated the event) if you can edit the current policy locally.

  Note that the current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by the system. Note also that this option appears only when **Drop when Inline** is enabled in the current policy.

- Edit — For standard text rule events, click **Edit** to modify the rule that generated the event. If the event is based on a shared object rule, a decoder, or a preprocessor, the rule is not available.

  Note If you edit a system-provided rule (as opposed to a custom standard text rule), you actually create a new local rule. Make sure you set the local rule to generate events and also disable the original rule in the current intrusion policy. Note, however, that you **cannot** enable local rules in the default policies.

- Generate events — Click **Set this rule to generate events...** to set the rule to generate events.

  If this event is generated by a standard text rule, you can set the rule to generate events in all policies that you can edit locally. Alternately, you can set the rule only in the current policy (that is, the policy that generated the event) if you can edit the current policy locally.

  Note that the current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by the system.

  Note You **cannot** set shared object rules to generate events from the packet view, nor can you disable rules in the default policies.

- Set suppression options — Expand **Set Suppression Options** and continue as described in Setting Suppression Options within the Packet View, on page 2428.

  You can use this option to suppress the rule that triggered this event in all policies that you can edit locally. Alternately, you can suppress the rule only in the current policy (that is, the policy that generated the event) if you can edit the current policy locally.

  Note that the current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by Cisco.

- Set threshold options — Expand **Set Thresholding Options** and continue as described in Setting Threshold Options within the Packet View, on page 2428.

  You can use this option to create a threshold for the rule that triggered this even in all policies that you can edit locally. Alternately, you create a threshold only for the current policy (that is, the policy that generated the event) if you can edit the current policy locally.

  Note that the current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default intrusion policy provided by the system.

- View documentation — Click **View Documentation** to learn more about the rule that generated the event. Optionally, then click **Rule Documentation** to view more-specific rule details.

Setting Threshold Options within the Packet View

You can control the number of events that are generated per rule over time by setting the threshold options in the packet view of an intrusion event. You can set threshold options in all policies that you can edit locally or, when it can be edited locally, only in the in the current policy (that is, the policy that caused the event to be generated).

Step 1 Within the packet view of an intrusion event that was generated by an intrusion rule, expand **Actions** in the Event Information section.

Step 2 Expand **Set Thresholding Options** and choose one of the two possible options:

- **in the current policy**
- **in all locally created policies**

Note The current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by the system.

Step 3 Choose the type of threshold you want to set:

- Click **limit** to limit notification to the specified number of event instances per time period.
- Click **threshold** to provide notification for each specified number of event instances per time period.
- Click **both** to provide notification once per time period after a specified number of event instances.

Step 4 Click the appropriate threshold to indicate whether you want the event instances tracked by **Source** or **Destination** IP address.

Step 5 In the **Count** field, enter the number of event instances you want to use as your threshold.

Step 6 In the **Seconds** field, enter a number between 1 and 86400 that specifies the time period for which event instances are tracked.

Step 7 If you want to override any current thresholds for this rule in existing intrusion policies, check the **Override any existing settings for this rule** check box.

Step 8 Click **Save Thresholding**.

Setting Suppression Options within the Packet View

You can use the suppression options to suppress intrusion events altogether, or based on the source or destination IP address. You can set suppression options in all policies that you can edit locally. Alternately, you can set suppression options only in the current policy (that is, the policy that generated the event) when the current policy can be edited locally.

Step 1 Within the packet view of an intrusion event that was generated by an intrusion rule, expand **Actions** in the Event Information section.

Step 2 Expand **Set Suppression Options** and click one of the two possible options:

- **in the current policy**
- **in all locally created policies**

Note The current policy option appears only when you can edit the current policy; for example, you can edit a custom policy, but you cannot edit a default policy provided by Cisco.

Step 3 Choose one of the following **Track By** options:

- Click **Source** to suppress events generated by packets originating from a specified source IP address.
- Click **Destination** to suppress events generated by packets going to a specified destination IP address.
- Click **Rule** to completely suppress events for the rule that triggered this event.

Step 4 In the **IP address or CIDR block** field, enter the IP address or CIDR block/prefix length you want to specify as the source or destination IP address.

Step 5 Click **Save Suppression**.

Related Topics

Firepower System IP Address Conventions, on page 17

Frame Information Fields

On the packet view, click the arrow next to **Frame** to view information about the captured frame. The packet view may display a single frame or multiple frames. Each frame provides information about an individual network packet. You would see multiple frames, for example, in the case of tagged packets or packets in reassembled TCP streams.

Frame n

The captured frame, where *n* is 1 for single-frame packets and the incremental frame number for multi-frame packets. The number of captured bytes in the frame is appended to the frame number.

Arrival Time

The date and time the frame was captured.

Time delta from previous captured frame

For multi-frame packets, the elapsed time since the previous frame was captured.

Time delta from previous displayed frame

For multi-frame packets, the elapsed time since the previous frame was displayed.

Time since reference or first frame

For multi-frame packets, the elapsed time since the first frame was captured.

Frame Number

The incremental frame number.

Frame Length

The length of the frame in bytes.

Capture Length

The length of the captured frame in bytes.

Frame is marked

Whether the frame is marked (true or false).

Protocols in frame

The protocols included in the frame.

The tag Keyword, on page 1741
TCP Stream Reassembly, on page 1879

Data Link Layer Information Fields

On the packet view, click the arrow next to the data link layer protocol (for example, **Ethernet II**) to view the data link layer information about the packet, which contains the 48-bit media access control (MAC) addresses for the source and destination hosts. It may also display other information about the packet, depending on the hardware protocol.

Note Note that this example discusses Ethernet link layer information; other protocols may also appear.

The packet view reflects the protocol used at the data link layer. The following listing describes the information you might see for an Ethernet II or IEEE 802.3 Ethernet packet in the packet view.

Destination

The MAC address for the destination host.

Note Ethernet can also use multicast and broadcast addresses as the destination address.

Source

The MAC address for the source host.

Type

For Ethernet II packets, the type of packet that is encapsulated in the Ethernet frame; for example, IPv6 or ARP datagrams. Note that this item only appears for Ethernet II packets.

Length

For IEEE 802.3 Ethernet packets, the total length of the packet, in bytes, not including the checksum. Note that this item only appears for IEEE 802.3 Ethernet packets.

Viewing Network Layer Information

On the packet view, click the arrow next to the network layer protocol (for example, **Internet Protocol**) to view more detailed information about network layer information related to the packet.

Note Note that this example discusses IP packets; other protocols may also appear.

IPv4 Network Layer Information Fields

The following listing describes protocol-specific information that might appear in an IPv4 packet.

Version

The Internet Protocol version number.

Header Length

The number of bytes in the header, including any IP options. An IP header with no options is 20 bytes long.

Differentiated Services Field

The values for differentiated services that indicate how the sending host supports Explicit Congestion Notification (ECN):

- `0x0` — does not support ECN-Capable Transport (ECT)
- `0x1` and `0x2` — supports ECT
- `0x3` — Congestion Experienced (CE)

Total Length

The length of the IP packet, in bytes, minus the IP header.

Identification

The value that uniquely identifies an IP datagram sent by the source host. This value is used to trace fragments of the same datagram.

Flags

The values that control IP fragmentation, where:

values for the Last Fragment flag indicate whether there are more fragments associated with the datagram:

- `0` — there are no more fragments associated with the datagram
- `1` — there are more fragments associated with the datagram

values for the Don't Fragment flag control whether the datagram can be fragmented:

- `0` — the datagram can be fragmented
- `1` — the datagram must **not** be fragmented

Fragment Offset

The value for the fragment offset from the beginning of the datagram.

Time to Live (ttl)

The remaining number of hops that the datagram can make between routers before the datagram expires.

Protocol

The transport protocol that is encapsulated in the IP datagram; for example, ICMP, IGMP, TCP, or UDP.

Header Checksum

The indicator for whether the IP checksum is valid. If the checksum is invalid, the datagram may have been corrupted during transit or may be being used in an intrusion evasion attempt.

Source/Destination

The IP address or domain name for the source (or destination) host.

Note that to display the domain name, you must enable IP address resolution.

Click the address or domain name to view the context menu, then select **Whois** to do a whois search on the host, **View Host Profile** to view host information, or choose an option to add the address to a global Block list or Do-Not-Block list.

IPv6 Network Layer Information Fields

The following listing describes protocol-specific information that might appear in an IPv6 packet.

Traffic Class

An experimental 8-bit field in the IPv6 header for identifying IPv6 packet classes or priorities similar to the differentiated services functionality provided for IPv4. When unused, this field is set to zero.

Flow Label

A optional 20-bit IPv6 hexadecimal value 1 to FFFFF that identifies a special flow such as non-default quality of service or real-time service. When unused, this field is set to zero.

Payload Length

A 16-bit field identifying the number of octets in the IPv6 payload, which is comprised of all of the packet following the IPv6 header, including any extension headers.

Next Header

An 8-bit field identifying the type of header immediately following the IPv6 header, using the same values as the IPv4 Protocol field.

Hop Limit

An 8-bit decimal integer that each node that forwards the packet decrements by one. The packet is discarded if the decremented value reaches zero.

Source

The 128-bit IPv6 address for the source host.

Destination

The 128-bit IPv6 address for the destination host.

Viewing Transport Layer Information

Step 1 On the packet view, click the arrow next to the transport layer protocol (for example, **TCP**, **UDP**, or **ICMP**).

Step 2 Optionally, click **Data** when present to view the first twenty-four bytes of the payload for the protocol immediately above it in the Packet Information section of the packet view.

Step 3 View the contents of the transport layer for TCP, UDP, and ICMP protocols as described in TCP Packet View Fields, on page 2433, UDP Packet View Fields, on page 2434, or ICMP Packet View Fields, on page 2435.

Note Note that these examples discuss TCP, UDP, and ICMP packets; other protocols may also appear.

TCP Packet View Fields

This section describes the protocol-specific information for a TCP packet.

Source port

The number that identifies the originating application protocol.

Destination port

The number that identifies the receiving application protocol.

Sequence number

The value for the first byte in the current TCP segment, keyed to initial sequence number in the TCP stream.

Next sequence number

In a response packet, the sequence number of the next packet to send.

Acknowledgement number

The TCP acknowledgement, which is keyed to the sequence number of the previously accepted data.

Header Length

The number of bytes in the header.

Flags

The six bits that indicate the TCP segment's transmission state:

- `U` — the urgent pointer is valid
- `A` — the acknowledgement number is valid
- `P` — the receiver should push data
- `R` — reset the connection
- `S` — synchronize sequence numbers to start a new connection
- `F` — the sender has finished sending data

Window size

The amount of unacknowledged data, in bytes, that the receiving host will accept.

Checksum

The indicator for whether the TCP checksum is valid. If the checksum is invalid, the datagram may have been corrupted during transit or may be being used in an in evasion attempt.

Urgent Pointer

The position, if present, in the TCP segment where the urgent data ends. Used in conjunction with the `U` flag.

Options

The values, if present, for TCP options.

UDP Packet View Fields

This section describes the protocol-specific information for a UDP packet.

Source port

The number that identifies the originating application protocol.

Destination port

The number that identifies the receiving application protocol.

Length

The combined length of the UDP header and data.

Checksum

The indicator for whether the UDP checksum is valid. If the checksum is invalid, the datagram may have been corrupted during transit.

ICMP Packet View Fields

This section describes the protocol-specific information for an ICMP packet.

Type

The type of ICMP message:

- 0 — echo reply
- 3 — destination unreachable
- 4 — source quench
- 5 — redirect
- 8 — echo request
- 9 — router advertisement
- 10 — router solicitation
- 11 — time exceeded
- 12 — parameter problem
- 13 — timestamp request
- 14 — timestamp reply
- 15 — information request (obsolete)
- 16 — information reply (obsolete)
- 17 — address mask request
- 18 — address mask reply

Code

The accompanying code for the ICMP message type. ICMP message types 3, 5, 11, and 12 have corresponding codes as described in RFC 792.

Checksum

The indicator for whether the ICMP checksum is valid. If the checksum is invalid, the datagram may have been corrupted during transit.

Viewing Packet Byte Information

On the packet view, click the arrow next to **Packet Bytes** to view hexadecimal and ASCII versions of the bytes that comprise the packet. If the system decrypted traffic, you can view the decrypted packet bytes.

Internally Sourced Intrusion Events

Intrusion events coming from internal sources indicate a compromised host on your network. If the source IP address is on your network, this is a sign that you shoud investigate this host.

The Intrusion Events Clipboard

The clipboard is a holding area where you can copy intrusion events from any of the intrusion event views.

The contents of the clipboard are sorted by the date and time that the events were generated. After you add intrusion events to the clipboard, you can delete them from the clipboard as well as generate reports on the contents of the clipboard.

You can also add intrusion events from the clipboard to incidents, which are compilations of events that you suspect are involved in a possible violation of your security policies.

Related Topics

Using Intrusion Event Workflows, on page 2419
Using the Intrusion Event Packet View, on page 2422
Creating an Incident, on page 2250

Generating Clipboard Reports

You can generate a report for the events on the clipboard just as you would from any of the event views.

Before you begin

- Add one or more events to the clipboard as described in Using Intrusion Event Workflows, on page 2419 or Using the Intrusion Event Packet View, on page 2422.

Step 1 Choose **Analysis** > **Intrusions** > **Clipboard**.

Step 2 You have the following options:

- To include specific events from a page on the clipboard, navigate to that page, check the check box next to the events, and click **Generate Report**.
- To include all the events from the clipboard, click **Generate Report All**.

Step 3 Specify how you want your report to look, then click **Generate**.

Step 4 Choose one or more output formats and, optionally, modify any of the other settings.

Step 5 Click **Generate**, then click **Yes**.

Step 6 You have the following choices:

- Click a report link to display the report in a new window.
- Click **OK** to return to the Report Templates page where you can modify your report design.

Related Topics

Report Templates, on page 2171

Deleting Events from the Clipboard

If you have intrusion events on the clipboard that you do not want to add to an incident, you can delete the events.

Note Deleting an event from the clipboard does **not** delete the event from the event database. However, deleting an event from the event database does delete the event from the clipboard.

Step 1 Choose **Analysis** > **Intrusions** > **Clipboard**.

Step 2 You have the following options:

- Delete specific events — To delete specific intrusion events from a page on the clipboard, navigate to the page, check the check box next to the events, and click **Delete**.
- Delete all events — To delete all the intrusion events from the clipboard, click **Delete All**. Note that if you choose the **Confirm 'All' Actions** option in the Event Preferences, you are first prompted to confirm that you want to delete all the events.

Viewing Intrusion Event Statistics

The Intrusion Event Statistics page provides you with a quick summary of the current state of your appliance and any intrusion events generated for your network.

Each of the IP addresses, ports, protocols, event messages, and so on shown on the page is a link. Click any link to view the associated event information. For example, if one of the top 10 destination ports is `80 (http)/tcp`, clicking that link displays the first page in the default intrusion events workflow, and lists the events targeting that port. Note that only the events (and the managed devices that generate events) in the current time range appear. Also, intrusion events that you have marked reviewed continue to appear in the statistics. For example, if the current time range is the past hour but the first event was generated five hours ago, when you click the **First Event** link, the resulting event pages will not show the event until you change the time range.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Overview** > **Summary** > **Intrusion Event Statistics**.

Step 2 From the two selection boxes at the top of the page, choose the zones and devices whose statistics you want to view, or choose **All Security Zones** and **All Devices** to view statistics for all the devices that are collecting intrusion events.

Step 3 Click **Get Statistics**.

Tip To view data from a custom time range, click the link in the upper right page area and follow the directions in Changing the Time Window, on page 2314.

Host Statistics

The Host Statistics section of the Intrusion Event Statistics page provides information about the appliance itself. On the Firepower Management Center, this section also provides information about any managed devices.

This information includes the following:

Time

The current time on the appliance.

Uptime

The number of days, hours, and minutes since the appliance itself was restarted. On the Firepower Management Center, the uptime also shows the last time each managed device was rebooted, the number of users logged in, and the load average.

Disk Usage

The percentage of the disk that is being used.

Memory Usage

The percentage of system memory that is being used.

Load Average

The average number of processes in the CPU queue for the past 1 minute, 5 minutes, and 15 minutes.

Event Overview

The Event Overview section of the Intrusion Event Statistics page provides an overview of the information in the intrusion event database.

These statistics include the following:

Events

The number of events in the intrusion event database.

Events in Time Range

The currently selected time range as well as the number and percentage of events from the database that fall within the time range.

First Event

The event message for the first event in the event database.

Last Event

The event message for the last event in the event database.

Note If you select a managed device while viewing intrusion event data on the Firepower Management Center, the Event Overview section for that device appears instead.

Event Statistics

The Event Statistics section of the Intrusion Event Statistics page provides more specific information about of the information in the intrusion event database.

This information includes details on:

- the top 10 event types
- the top 10 source IP addressees
- the top 10 destination IP addresses
- the top 10 destination ports
- the protocols, ingress and egress security zones, and devices with the greatest number of events

Note In a multidomain deployment, the system builds a separate network map for each leaf domain. As a result, a leaf domain can contain an IP address that is unique within its network, but identical to an IP address in another leaf domain. When you view event statistics in an ancestor domain, the system may display multiple instances of that repeated IP address. At first glance, they might appear to be duplicate entries. However, if you drill down to the host profile information for each IP address, the system shows that they belong to different leaf domains.

Viewing Intrusion Event Performance Graphs

The intrusion event performance page allows you to generate graphs that depict performance statistics for intrusion events over a specific period of time for a Firepower Management Center or a managed device. Graphs can be generated to reflect number of intrusion events per second, number of megabits per second, average number of bytes per packet, the percent of packets uninspected by Snort, and the number of packets blocked as the result of TCP normalization. These graphs can show statistics for the last hour, last day, last week, or last month of operation.

Note New data is accumulated for statistics graphs every five minutes. Therefore, if you reload a graph quickly, the data may not change until the next five-minute increment occurs. Each graph displays *average* values in the intervals shown (day, hour, or five minutes) for the selected time period (last month, week, day, or hour). Decimal values are displayed when the average is less than one.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Overview** > **Summary** > **Intrusion Event Performance**.

Step 2 From the **Select Device** list, choose the devices whose data you want to view.

Step 3 From the **Select Graph(s)** list, choose the type of graph you want to create as described in Intrusion Event Performance Statistics Graph Types, on page 2440.

Step 4 From the **Select Time Range** list, choose the time range you would like to use for the graph.

Step 5 Click **Graph**.

Step 6 To save the graph, right-click it and follow the instructions for your browser to save the image.

Intrusion Event Performance Statistics Graph Types

The following table lists the available graph types. Note that graph types display differently if they are populated with data affected by the network analysis policy **Inline Mode** setting. If **Inline Mode** is disabled, the graph types marked with an asterisk (`*`) in the web interface (a `yes` in the column below) populate with data about the traffic the system would have modified or dropped if **Inline Mode** was enabled..

Table 323: Intrusion Event Performance Graph Types

To generate data for...	You must...	Which represents...	Affected by Inline Mode?
Avg Bytes/Packet	n/a	the average number of bytes included in each packet.	no
ECN Flags Normalized in TCP Traffic/Packet	enable **Explicit Congestion Notification** and select **Packet**	the number of packets for which ECN flags have been cleared on a per-packet basis regardless of negotiation.	yes
ECN Flags Normalized in TCP Traffic/Session	enable **Explicit Congestion Notification** and select **Stream**	the number of times that ECN flags have been cleared on a per-stream basis when ECN use was not negotiated.	yes
Events/Sec	n/a	the number of events per second generated on the device.	no
ICMPv4 Echo Normalizations	enable **Normalize ICMPv4**	the number of ICMPv4 packets for which the 8-bit Code field in Echo (Request) or Echo Reply messages were cleared.	yes
ICMPv6 Echo Normalizations	enable **Normalize ICMPv6**	the number of ICMPv6 packets for which the 8-bit Code field in Echo (Request) or Echo Reply messages was cleared.	yes

To generate data for...	You must...	Which represents...	Affected by Inline Mode?
IPv4 DF Flag Normalizations	enable **Normalize IPv4** and **Normalize Don't Fragment Bit**	the number of IPv4 packets for which the single-bit Don't Fragment subfield of the IPv4 Flags header field was cleared.	yes
IPv4 Options Normalizations	enable **Normalize IPv4**	the number of IPv4 packets for which the option octet was set to 1 (No Operation).	yes
IPv4 Reserved Flag Normalizations	enable **Normalize IPv4** and **Normalize Reserved Bit**	the number of IPv4 packets for which the single-bit Reserved subfield of the IPv4 Flags header field was cleared.	yes
IPv4 Resize Normalizations	enable **Normalize IPv4**	the number of IPv4 packets with excessive-length payload that have been truncated to the datagram length specified in the IP header.	yes
IPv4 TOS Normalizations	enable **Normalize IPv4** and **Normalize TOS Bit**	the number of IPv4 packets for which the one-byte Differentiated Services (DS) field (formerly known as the Type of Service (TOS) field) was cleared.	yes
IPv4 TTL Normalizations	enable **Normalize IPv4**, **Maximum TTL**, and **Reset TTL**	the number of IPv4 Time to Live normalizations.	yes
IPv6 Options Normalizations	enable **Normalize IPv6**	the number of IPv6 packets for which the Option Type field in the Hop-by-Hop Options or Destination Options extension header was set to `00` (Skip and continue processing).	yes
IPv6 TTL Normalizations	enable **Normalize IPv6**, **Minimum TTL**, and **Reset TTL**	the number of IPv6 Hop Limit (TTL) normalizations.	yes
Mbits/Sec	n/a	the number of megabits per second of traffic that passes through the device.	no
Packet Resized to Fit MSS Normalizations	enable **Trim Data to MSS**	the number of packets for which the payload was longer than the TCP Data field, so the payload was trimmed to the Maximum Segment Size.	yes

To generate data for...	You must...	Which represents...	Affected by Inline Mode?
Packet Resized to Fit TCP Window Normalizations	enable **Trim Data to Window**	the number of packets for which the TCP Data field was trimmed to fit the receiving host's TCP window.	yes
Percent Packets Dropped	n/a	the average percentage of uninspected packets across all selected devices. For example, if you select two devices, then an average of 50% may indicate that one device has a 90% drop rate and the other has a 10% drop rate. It may also indicate that both devices have a drop rate of 50%. The graph only represents the total % drop when you select a single device.	no
RST Packets With Data Stripped Normalizations	enable **Remove Data on RST**	the number of packets for which data was removed from a TCP reset (RST) packet.	yes
SYN Packets With Data Stripped Normalizations	enable **Remove Data on SYN**	the number of packets for which data was removed from SYN packets when the TCP operating system was not Mac OS.	yes
TCP Header Padding Normalizations	enable **Normalize/Clear Option Padding Bytes**	the number of TCP packets in which option padding bytes were set to 0.	yes
TCP No Option Normalizations	enable **Allow These TCP Options** and set to an option other than `any`	the number of packets from which the Time Stamp option was stripped.	yes
TCP NS Flag Normalizations	enable **Explicit Congestion Notification** and select **Packet**	the number of ECN Nonce Sum (NS) option normalizations.	yes
TCP Options Normalizations	enable **Allow These TCP Options** and set to an option other than `any`	the number of options (excluding MSS, Window Scale, Time Stamp, and explicitly allowed options) for which the option field is set to No Operation (TCP Option 1).	yes
TCP Packets Blocked By Normalizations	enable **Normalize TCP Payload** (segment reassembly must fail)	the number of packets dropped because the TCP segments could not be properly reassembled.	yes

To generate data for...	You must...	Which represents...	Affected by Inline Mode?
TCP Reserved Flags Normalizations	enable **Normalize/Clear Reserved Bits**	the number of TCP packets where the Reserved bits have been cleared.	yes
TCP Segment Reassembly Normalizations	enable **Normalize TCP Payload** (segment reassembly must be successful)	the number of packets for which the TCP Data field was normalized to ensure consistency in retransmitted data (any segments that cannot be properly reassembled are dropped).	yes
TCP SYN Option Normalizations	enable **Allow These TCP Options** and set to an option other than `any`	the number of options for which the Maximum Segment Size or Window Scale option was set to No Operation (TCP Option 1) because the SYN control bit was not set.	yes
TCP Timestamp ECR Normalizations	enable **Allow These TCP Options** and set to an option other than `any`	the number of packets for which the Time Stamp Echo Reply (TSecr) option field was cleared because the Acknowledgment (ACK) control bit was not set.	yes
TCP Urgent Pointer Normalizations	enable **Normalize Urgent Pointer**	the number of packets for which the two-byte TCP header Urgent Pointer field was greater than the payload length and was set to the payload length.	yes
Total Blocked Packets	configure **Inline Mode** or **Drop when Inline**	the total number of dropped packets, including rule, decoder, and preprocessor drops.	no
Total Injected Packets	configure **Inline Mode**	the number of packets that were resized before being retransmitted.	no
Total TCP Filtered Packets	configure TCP Stream Preprocessing	the number of packets skipped by the stream because of TCP port filtering.	no
Total UDP Filtered Packets	configure UDP Stream Preprocessing	the number of packets skipped by the stream because of UDP port filtering.	no
Urgent Flag Cleared Normalizations	enable **Clear URG if Urgent Pointer is Not Set**	the number of packets for which the TCP header URG control bit was cleared because the urgent pointer was not set.	yes

To generate data for...	You must...	Which represents...	Affected by Inline Mode?
Urgent Pointer and Urgent Flag Cleared Normalizations	enable **Clear Urgent Pointer/URG on Empty Payload**	the number of packets for which the TCP header Urgent Pointer field and the URG control bit have been cleared because there was no payload.	yes
Urgent Pointer Cleared Normalizations	enable **Clear Urgent Pointer if URG=0**	the number of packets for which the 16-bit TCP header Urgent Pointer field was cleared because the urgent (URG) control bit was not set.	yes

Viewing Intrusion Event Graphs

The Firepower System provides graphs that show you intrusion event trends over time. You can generate intrusion event graphs over time ranging from the last hour to the last month, for one or all managed devices.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Overview** > **Summary** > **Intrusion Event Graphs**.

Step 2 Under **Select Device**, choose **all** to include all devices, or choose the specific device you want to include in the graph.

Step 3 Under **Select Graph(s)**, choose the type of graph you want to generate:

- Top 10 Destination Ports
- Top 10 Source IP Addresses
- Top 10 Event Messages

Step 4 Under **Select Time Range**, choose the time range for the graph:

- Last Hour
- Last Day
- Last Week
- Last Month

Step 5 Click **Graph**.

History for Intrusion Events

Feature	Version	Details
Unique identifier for connection event in syslogs	6.4.0.4	The following syslog fields collectively uniquely identify a connection event and appear in syslogs for intrusion events: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.
IntrusionPolicy field is now included in syslog	6.4	Intrusion event syslogs now specify the intrusion policy that triggered the event.
New intrusion event search field: CVE ID	6.4	You can now search by MITRE's Common Vulnerabilities and Exposures identification number Modified screens: **Analysis > Intrusions > Events > Edit Search** Supported Platforms: All.

CHAPTER 122

File/Malware Events and Network File Trajectory

The following topics provide an overview of file and malware events, local malware analysis, dynamic analysis, captured files, and network file trajectories.

About File/Malware Events and Network File Trajectory

File policies automatically generate file and malware events for matched traffic, and log captured file information. When a file policy generates a file or malware event, or captures a file, the system also automatically logs the end of the associated connection to the Firepower Management Center database. You can analyze this data to address any negative impacts and block future attacks.

Based on the file analysis results, you can review captured files and generated malware and file events using tables on pages available under the Analysis > Files menu. When available, you can examine a file's composition, disposition, threat score, and dynamic analysis summary report for further insight into the malware analysis.

To further target your analysis, you can use a malware file's *network file trajectory* (a map of how the file traversed your network, passing among hosts, as well as various file properties) to track the spread of an individual threat across hosts over time, allowing you to concentrate outbreak control and prevention efforts where most useful.

If you configure local malware analysis or dynamic analysis in a file rule, the system preclassifies files matching the rule and generates a file composition report.

If your organization has deployed *AMP for Endpoints* and integrated that deployment with your Firepower Management Center, you can also import records of scans, malware detections, and quarantines, as well as indications of compromise (IOC) identified by that product. This data is displayed alongside event data gathered by Firepower for a more complete picture of malware on your network.

The Context Explorer, dashboards, and reporting features can also aid a deeper understanding of the files and malware detected, captured, and blocked. You can also use events to trigger correlation policy violations, or alert you via email, SMTP, or syslog.

Note To configure your system to detect malware and generate file and malware events, see File Policies and Malware Protection, on page 1459.

File and Malware Events

The Firepower Management Center can log various types of file and malware events. The information available for any individual event can vary depending on how and why it was generated:

- *File events* represent files, including malware, detected by the Firepower system (AMP for Networks.) File events do not contain AMP for Endpoints-related fields.
- *Malware events* represent malware detected by either AMP for Networks or AMP for Endpoints; malware events can also record data other than threats from your AMP for Endpoints deployment, such as scans and quarantines.
- *Retrospective malware events* represent files detected by AMP for Networks whose dispositions (whether the files are malware) have changed.

Note

- Files identified as malware by AMP for Networks generate both a file event and a malware event. Malware events generated by AMP for Endpoints do not have corresponding file events.
- File events generated by inspecting NetBIOS-ssn (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.
- The Firepower System supports the display and input of file names that use Unicode (UTF-8) characters. However, Unicode file names appear in PDF reports in transliterated form. Additionally, the SMB protocol replaces unprintable characters in file names with periods.

File and Malware Event Types

File Events

The system logs the file events generated when a managed device detects or blocks a file in network traffic, according to the rules in currently deployed file policies.

When the system generates a file event, the system also logs the end of the associated connection to the Firepower Management Center database, regardless of the logging configuration of the invoking access control rule.

Malware Events

The Firepower system (specifically the AMP for Networks feature) generates malware events when it detects malware in network traffic as part of your overall access control configuration. Malware events contain the disposition of the resulting event and contextual data about how, where, and when the malware was detected.

Table 324: Malware Event Generation Scenarios

When the system detects a file and...	Disposition
successfully queries the AMP cloud (performs a malware cloud lookup) for the file's disposition	Malware, Clean, or Unknown
queries the AMP cloud but cannot establish a connection or the cloud is otherwise unavailable	Unavailable You may see a small percentage of events with this disposition; this is expected behavior.
the threat score associated with a file exceeds the malware threshold threat score defined in the file policy that detected the file, or local malware analysis identifies malware	Malware
it is on the custom detection list (manually marked as malware)	Custom Detection
it is on the on the clean list (manually marked as clean),	Clean

Retrospective Malware Events

For malware detected in network traffic, dispositions can change. For example, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file you queried in the last week, the AMP cloud notifies the system. Then, two things happen:

- The Firepower Management Center generates a new retrospective malware event.

  This new retrospective malware event represents a disposition change for all files detected in the last week that have the same SHA-256 hash value. For that reason, these events contain limited information: the date and time the Firepower Management Center was notified of the disposition change, the new disposition, the SHA-256 hash value of the file, and the threat name. They do not contain IP addresses or other contextual information.

- The Firepower Management Center changes the file disposition for previously detected files with the retrospective event's associated SHA-256 hash value.

  If a file's disposition changes to Malware, the Firepower Management Center logs a new malware event to its database. Except for the new disposition, the information in this new malware event is identical to that in the file event generated when the file was initially detected.

  If a file's disposition changes to Clean, the Firepower Management Center does not delete the malware event. Instead, the event reflects the change in disposition. This means that files with clean dispositions can appear in the malware table, but only if they were originally thought to be malware. Files that were never identified as malware appear only in the files table.

Malware Events Generated by AMP for Endpoints

If your organization uses AMP for Endpoints, individual users install lightweight connectors on *endpoints*: computers and mobile devices. Connectors can inspect files upon upload, download, execution, open, copy, move, and so on. These connectors communicate with the AMP cloud to determine if inspected files contain malware.

When a file is positively identified as malware, the AMP cloud sends the threat identification to the Firepower Management Center. The AMP cloud can also send other kinds of information to the Firepower Management Center, including data on scans, quarantines, blocked executions, and cloud recalls. The Firepower Management Center logs this information as malware events.

Note The IP addresses reported in malware events generated by AMP for Endpoints may not be in your network map—and may not even be in your monitored network at all. Depending on your deployment, level of compliance, and other factors, endpoints in your organization monitored by AMP for Endpoints may not be the same hosts as those monitored by AMP for Networks.

Malware Event Analysis with AMP for Endpoints

If your organization has deployed Cisco AMP for Endpoints:

- You can configure the system to display malware events detected by AMP for Endpoints on Firepower Management Center event pages, alongside events detected by AMP for Networks.
- If you are using the AMP public cloud, you can view file trajectory and other information about a particular SHA in AMP for Endpoints.

To configure the above functionality, see Integrate Firepower and AMP for Endpoints, on page 1494.

Event Data from AMP for Endpoints

If your organization has deployed AMP for Endpoints for malware protection, you can configure the system to let you work in FMC with file and malware data from AMP for Endpoints.

However, you should be aware of the differences between file and malware data from AMP for Endpoints and file and malware data from AMP for Networks (malware protection using the Firepower system.)

Because AMP for Endpoints malware detection is performed at the endpoint at download or execution time, while managed devices detect malware in network traffic, the information in the two types of malware events is different. For example, malware events detected by AMP for Endpoints ("endpoint-based malware") contain information on file path, invoking client application, and so on, while malware detections in network traffic contain port, application protocol, and originating IP address information about the connection used to transmit the file.

As another example, for malware events detected by AMP for Networks ("network-based malware events"), user information represents the user most recently logged into the host where the malware was destined, as determined by network discovery. But AMP for Endpoints-reported users represent the user currently logged into the endpoint where the malware was detected.

Note Depending on your deployment, endpoints monitored by AMP for Endpoints may not be the same hosts as those monitored by AMP for Networks. For this reason, malware events generated by AMP for Endpoints do not add hosts to the network map. However, the system uses IP and MAC address data to tag monitored hosts with indications of compromise obtained from your AMP for Endpoints deployment. If two different hosts monitored by different AMP solutions have the same IP and MAC address, the system can incorrectly tag monitored hosts with AMP for Endpoints IOCs.

The following table summarizes the differences between the event data generated by Firepower when using a Malware license, and event data generated by AMP for Endpoints.

Table 325: Summary of Data Differences Between AMP Products

Feature	AMP for Networks	AMP for Endpoints
Events generated	File events, captured files, malware events, and retrospective malware events	Malware events
Information in malware events	Basic malware event information, plus connection data (IP address, port, and application protocol)	In-depth malware event information; no connection data
Network file trajectory	FMC-based	FMC and the AMP for Endpoints management console each have a network file trajectory. Both are useful.

Using File and Malware Event Workflows

Use this procedure to view file and malware events in a table and to manipulate the event view depending on the information relevant to your analysis. The page you see when you access events differs depending on the workflow, which is simply a series of pages you can use to evaluate events by moving from a broad to a more focused view. You can also create a custom workflow that displays only the information that matches your specific needs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

You must be an Admin or Security Analyst user to perform this task.

Choose one of the following:

- **Analysis** > **Files** > **File Events**
- **Analysis** > **Files** > **Malware Events**

Tip In the table view of events, several fields are hidden by default. To show a hidden field in an event view, expand the search constraints, then click the field name under **Disabled Columns**.

Tip To quickly view the connections where specific files were detected, choose the files using the check boxes in the table, then choose **Connections Events** from the **Jump to** drop-down list.

Tip Right-click an item in the table to see options. (Not every column offers options.)

File and Malware Event Fields

File and malware events, which you can view and search using workflows, contain the fields listed in this section. Keep in mind that the information available for any individual event can vary depending on how and why it was generated.

Note Files identified as malware by AMP for Networks generate both a file event and a malware event. Malware events generated by AMP for Endpoints do not have corresponding file events, and file events do not have AMP for Endpoints-related fields.

Syslog messages are populated with initial values and do not update, even if the equivalent field in the FMC web interface is updated, for example with a retrospective verdict.

Action (Syslog: FileAction)

The action associated with file policy rule that detected the file, and any associated file rule action options.

AMP Cloud

The name of the AMP cloud where the AMP for Endpoints event originated.

Application File Name

The client application accessing the malware file when AMP for Endpoints detection occurred. These applications are **not** tied to network discovery or application control.

Application File SHA256

The SHA-256 hash value of the parent file accessing the AMP for Endpoints-detected or quarantined file when detection occurred.

Application Protocol (Syslog: ApplicationProtocol)

The application protocol used by the traffic in which a managed device detected the file.

Application Protocol Category or Tag

The criteria that characterize the application to help you understand the application's function.

Application Risk

The risk associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated risk; this field displays the highest of those.

Archive Depth (Syslog: ArchiveDepth)

The level (if any) at which the file was nested in an archive file.

Archive Name (Syslog: ArchiveFileName)

The name of the archive file (if any) which contained the malware file.

To view the contents of an archive file, go to any table under **Analysis > Files** that lists the archive file, right-click on the archive file's table row to open the context menu, then click **View Archive Contents**.

Archive SHA256 (Syslog: ArchiveSHA256)

The SHA-256 hash value of the archive file (if any) which contains the malware file.

To view the contents of an archive file, go to any table under Analysis > Files that lists the archive file, right-click on that archive file's table row to open the context menu, then click **View Archive Contents**.

ArchiveFileStatus (Syslog Only)

The status of an archive being inspected. Can have the following values:

- Pending — Archive is being inspected
- Extracted — Successfully inspected without any problems
- Failed — Failed to inspect, insufficient system resources
- Depth Exceeded — Successful, but archive exceeded the nested inspection depth
- Encrypted — Partially successful, archive was or contains an archive that is encrypted
- Not Inspectable — Partially successful, file is possibly malformed or corrupt

Business Relevance

The business relevance associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those.

Category / File Type Category

The general categories of file type, for example: Office Documents, Archive, Multimedia, Executables, PDF files, Encoded, Graphics, or System Files.

Client (Syslog: Client)

The client application that runs on one host and relies on a server to send a file.

Client Category or Tag

The criteria that characterize the application to help you understand the application's function.

Connection Counter (Syslog Only)

A counter that distinguishes one connection from another simultaneous connection. This field has no significance on its own.

The follwing fields collectively uniquely identify the connection event associated with a particular file or malware event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Connection Instance ID (Syslog Only)

The Snort instance that processed the connection event. This field has no significance on its own.

The follwing fields collectively uniquely identify the connection event associated with a particular file or malware event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Count

After you apply a constraint that creates two or more identical rows, the number of events that match the information in each row.

Detection Name

The name of the detected malware.

Detector

The AMP for Endpoints detector that identified the malware, such as ClamAV, Spero, or SHA.

Device

For file events and for malware events generated by Firepower devices, the name of the device that detected the file.

For malware events generated by AMP for Endpoints and for retrospective malware events generated by the AMP cloud, the name of the Firepower Management Center.

DeviceUUID (Syslog Only)

The unique identifier of the Firepower device that generated an event.

The follwing fields collectively uniquely identify the connection event associated with a particular file or malware event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

Disposition / File Disposition (Syslog: SHA_Disposition)

The file’s disposition:

Malware

Indicates that the AMP cloud categorized the file as malware, local malware analysis identified malware, or the file's threat score exceeded the malware threshold defined in the file policy.

Clean

Indicates that the AMP cloud categorized the file as clean, or that a user added the file to the clean list. Clean files appear in the malware table only if they were changed to clean.

Unknown

Indicates that the system queried the AMP cloud, but the file has not been assigned a disposition; in other words, the AMP cloud has not categorized the file.

Custom Detection

Indicates that a user added the file to the custom detection list.

Unavailable

Indicates that the system could not query the AMP cloud. You may see a small percentage of events with this disposition; this is expected behavior.

N/A

Indicates a Detect Files or Block Files rule handled the file and the Firepower Management Center did not query the AMP cloud.

File dispositions appear only for files for which the system queried the AMP cloud.

Syslog fields reflect only the initial disposition; they do not update to reflect retrospective verdicts.

Domain

For file events and for malware events generated by Firepower devices, the domain of the device that detected the file. For malware events generated by AMP for Endpoints and for retrospective malware events generated by the AMP cloud, the domain associated with the AMP cloud connection that reported the event.

This field is only present if you have ever configured the Firepower Management Center for multitenancy.

DstIP (Syslog Only)

The IP address of the host that responded to the connection. This may be the IP address of the sender or the recipient of the file, depending on the value in the FileDirection field:

If FileDirection is `Upload`, then this is the IP address of the file recipient.

If FileDirection is `Download`, then this is the IP address of the file sender.

See also **SrcIP**.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

DstPort (Syslog Only)

The port used in the connection described under **DstIP**.

Event Subtype

The AMP for Endpoints action that led to malware detection, for example, Create, Execute, Move, or Scan.

Event Type

The sub-type of malware event.

File Name (Syslog: FileName)

The name of the file.

File Path

The file path of the malware file detected by AMP for Endpoints, not including the file name.

File Policy (Syslog: FilePolicy)

The file policy that detected the file.

File Storage / Stored (Syslog: FileStorageStatus)

The storage status of the file associated with the event:

Stored

Returns all events where the associated file is currently stored.

Stored in connection

Returns all events where the system captured and stored the associated file, regardless of whether the associated file is currently stored.

Failed

Returns all events where the system failed to store the associated file.

Syslog fields contain only the initial status; they do not update to reflect changed status.

File Timestamp

The time and date that AMP for Endpoints detected the malware file was created.

FileDirection (Syslog Only)

Whether the file was downloaded or uploaded during the connection. Possible values are:

- Download — the file was transferred from the DstIP to the SrcIP.
- Upload — the file was transferred from the SrcIP to the DstIP.

FileSandboxStatus (Syslog Only)

Indicates whether the file was sent for dynamic analysis and if so, the status.

First Packet Time (Syslog Only)

The time the system encountered the first packet.

The follwing fields collectively uniquely identify the connection event associated with a particular file or malware event: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.

FirstPacketSecond (Syslog Only)

The time at which the file download or upload flow started.

The time the event occurred is captured in the message header timestamp.

HTTP Response Code

The HTTP status code sent in response to a client's HTTP request when a file is transferred.

IOC

Whether the malware event triggered an indication of compromise (IOC) against a host involved in the connection. When AMP for Endpoints data triggers an IOC rule, a full malware event is generated, with the type AMP IOC.

Message

Additional information associated with a malware event. For file events and for malware events generated by Firepower devices, this field is populated only for files whose disposition has changed, that is, that have an associated retrospective event.

Protocol (Syslog Only)

The protocol used for the connection, for example TCP or UDP.

Receiving Continent

The continent of the host receiving the file.

Receiving Country

The country of the host receiving the file.

Receiving IP

In the FMC web interface:

For file events and for malware events generated by Firepower devices, the IP address of the host receiving the file.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

For malware events generated by AMP for Endpoints, the IP address of the endpoint whose connector reported the event.

For syslog equivalents (events generated by Firepower devices only), see **DstIP** and **SrcIP**.

Receiving Port

In the FMC web interface:

The destination port used by the traffic where the file was detected.

For syslog equivalents, see **DstIP** and **SrcIP** and **DstPort** and **SrcPort**.

Security Context (Syslog: Context)

The metadata identifying the virtual firewall group through which the traffic passed. Note that the system only displays this field when managing at least one ASA FirePOWER device that is running in multiple context mode.

Sending Continent

The continent of the host sending the file.

Sending Country

The country of the host sending the file.

Sending IP

In the FMC web interface: The IP address of the host sending the file.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

For syslog equivalents, see **DstIP** and **SrcIP**.

Sending Port

In the FMC web interface:

The source port used by the traffic where the file was detected.

For syslog equivalents, see **DstIP** and **SrcIP** and **DstPort** and **SrcPort**.

SHA256 / File SHA256 (Syslog: FileSHA256)

The SHA-256 hash value of the file.

To have a SHA256 value, the file must have been handled by one of:

- a Detect Files file rule with **Store files** enabled
- a Block Files file rule with **Store files** enabled
- a Malware Cloud Lookup file rule
- a Block Malware file rule
- AMP for Endpoints

This column also displays a network file trajectory icon that represents the most recently detected file event and file disposition, and that links to the network file trajectory.

Size (KB) / File Size (KB) (Syslog: FileSize)

In the FMC web interface: The size of the file, in kilobytes.

In syslog messages: The size of the file, in bytes.

Note that if the system determines the file type of a file before the file is fully received, the file size may not be calculated. In this case, this field is blank.

SperoDisposition (Syslog Only)

Indicates whether the SPERO signature was used in file analysis. Possible values:

- Spero detection performed on file
- Spero detection not performed on file

SrcIP (Syslog Only)

The IP address of the host that initiated the connection. This may be the IP address of the sender or the recipient of the file, depending on the value in the FileDirection field:

If FileDirection is **`Upload`**, this is the IP address of the file sender.

If FileDirection is **`Download`**, this is the IP address of the file recipient.

See also **DstIP**.

See also A Note About Initiator/Responder, Source/Destination, and Sender/Receiver Fields, on page 2385.

SrcPort (Syslog Only)

The port used in the connection described under **SrcIP**.

SSL Actual Action (Syslog: SSLActualAction)

The action the system applied to encrypted traffic:

Block or Block with reset

Represents blocked encrypted connections.

Decrypt (Resign)

Represents an outgoing connection decrypted using a re-signed server certificate.

Decrypt (Replace Key)

Represents an outgoing connection decrypted using a self-signed server certificate with a substituted public key.

Decrypt (Known Key)

Represents an incoming connection decrypted using a known private key.

Default Action

Indicates the connection was handled by the default action.

Do not Decrypt

Represents a connection the system did not decrypt.

Field values are displayed in the **SSL Status** field on the search workflow pages.

SSL Certificate Information

The information stored on the public key certificate used to encrypt traffic, including:

- Subject/Issuer Common Name
- Subject/Issuer Organization

- Subject/Issuer Organization Unit
- Not Valid Before/After
- Serial Number, Certificate Fingerprint
- Public Key Fingerprint

For syslog, see **SSLCertificate**.

SSL Failure Reason (Syslog: SSLFlowStatus)

The reason the system failed to decrypt encrypted traffic:

- Unknown
- No Match
- Success
- Uncached Session
- Unknown Cipher Suite
- Unsupported Cipher Suite
- Unsupported SSL Version
- SSL Compression Used
- Session Undecryptable in Passive Mode
- Handshake Error
- Decryption Error
- Pending Server Name Category Lookup
- Pending Common Name Category Lookup
- Internal Error
- Network Parameters Unavailable
- Invalid Server Certificate Handle
- Server Certificate Fingerprint Unavailable
- Cannot Cache Subject DN
- Cannot Cache Issuer DN
- Unknown SSL Version
- External Certificate List Unavailable
- External Certificate Fingerprint Unavailable
- Internal Certificate List Invalid
- Internal Certificate List Unavailable

- Internal Certificate Unavailable
- Internal Certificate Fingerprint Unavailable
- Server Certificate Validation Unavailable
- Server Certificate Validation Failure
- Invalid Action

Field values are displayed in the **SSL Status** field on the search workflow pages.

SSL Status

The action associated with the **SSL Actual Action** (SSL rule, default action, or undecryptable traffic action) that logged the encrypted connection. The **Lock icon** links to TLS/SSL certificate details. If the certificate is unavailable (for example, for connections blocked due to TLS/SSL handshake error), the lock icon is grayed out.

If the system fails to decrypt an encrypted connection, it displays the **SSL Actual Action** (undecryptable traffic action) taken, as well as the **SSL Failure Reason**. For example, if the system detects traffic encrypted with an unknown cipher suite and allows it without further inspection, this field displays `Do Not Decrypt (Unknown Cipher Suite)`.

When searching this field, type one or more of the **SSL Actual Action** and **SSL Failure Reason** values to view encrypted traffic the system handled or failed to decrypt.

SSL Subject/Issuer Country

The two-character ISO 3166-1 alpha-2 country code for the subject or issuer country associated with the encryption certificate.

SSLCertificate (Syslog Only)

The certificate fingerprint of the TLS/SSL server.

Threat Name (Syslog: ThreatName)

The name of the detected malware.

Threat Score (Syslog: ThreatScore)

The threat score most recently associated with this file. This is a value from 0 to 100 based on the potentially malicious behaviors observed during dynamic analysis.

The threat score icon links to the Dynamic Analysis Summary report.

Time

The date and time the event was generated. This field is not searchable.

In syslog messages, see **FirstPacketSecond**.

Type / File Type (Syslog: FileType)

The type of file, for example, HTML or MSEXE.

URI / File URI (Syslog: URI)

The URI of the connection associated with the file transaction, for example, the URL from which a user downloaded the file.

User (Syslog: User)

The username associated with the IP address that initiated the connection. If this IP address is external to your network, the associated username is typically unknown.

If applicable, the username is preceded by `<realm>\`.

For file events and for malware events generated by Firepower devices, this user is determined by network discovery.

For malware events generated by AMP for Endpoints, AMP for Endpoints determines user names. These users **cannot** be tied to user discovery or control. They do not appear in the Users table, nor can you view details for these users.

Web Application (Syslog: WebApplication)

The application that represents the content or requested URL for HTTP traffic detected in the connection.

Web Application Category or Tag

Criteria that characterize the application to help you understand the application's function.

Malware Event Sub-Types

The following table lists the malware event subtypes, whether a malware event generated by AMP for Networks (a "network-based malware event") or AMP for Endpoints (an "endpoint-based malware event") can have that subtype, and whether the system uses that subtype to build network file trajectories.

Table 326: Malware Event Types

Malware Event Subtype/Search Value	AMP for Networks	AMP for Endpoints	File Trajectory
Threat Detected in Network File Transfer	yes	no	yes
Threat Detected in Network File Transfer (retrospective)	yes	no	yes
Threat Detected	no	yes	yes
Threat Detected in Exclusion	no	yes	yes
Threat Quarantined	no	yes	yes
AMP IOC (Indications of compromise)	no	yes	no
Blocked Execution	no	yes	no
Cloud Recall Quarantine	no	yes	no

Malware Event Subtype/Search Value	AMP for Networks	AMP for Endpoints	File Trajectory
Cloud Recall Quarantine Attempt Failed	no	yes	no
Cloud Recall Quarantine Started	no	yes	no
Cloud Recall Restore from Quarantine	no	yes	no
Cloud Recall Restore from Quarantine Failed	no	yes	no
Cloud Recall Restore from Quarantine Started	no	yes	no
Quarantine Failure	no	yes	no
Quarantined Item Restored	no	yes	no
Quarantine Restore Failed	no	yes	no
Quarantine Restore Started	no	yes	no
Scan Completed, No Detections	no	yes	no
Scan Completed With Detections	no	yes	no
Scan Failed	no	yes	no
Scan Started	no	yes	no

Information Available in File and Malware Event Fields

The following table lists whether the system displays information for each file and malware event field.

If your organization has deployed AMP for Endpoints and integrated that product with your Firepower deployment:

- Malware events and indications of compromise (IOCs) imported from your AMP for Endpoints deployment do not contain contextual connection information, but they do include information obtained at download or execution time, such as file path, invoking client application, and so on.
- File event table views do not display AMP for Endpoints-related fields.

Table 327: Information Available in File and Malware Event Fields

Field	File Event	Malware Events Detected by the Firepower System	Retrospective Events Detected by the Firepower System	Malware Events Detected by AMP for Endpoints
Action	yes	yes	yes	no

Field	File Event	Malware Events Detected by the Firepower System	Retrospective Events Detected by the Firepower System	Malware Events Detected by AMP for Endpoints
AMP Cloud	no	no	no	yes
Application File Name	no	no	no	yes
Application File SHA256	no	no	no	yes
Application Protocol	yes	yes	no	no
Application Protocol Category or Tag	yes	yes	yes	no
Application Risk	yes	yes	yes	no
Archive Depth	yes	yes	no	yes
Archive Name	yes	yes	no	yes
Archive SHA256	yes	yes	no	yes
Business Relevance	yes	yes	yes	no
Category / File Type Category	yes	yes	no	yes
Client	yes	yes	yes	no
Client Category or Tag	yes	yes	yes	no
Count	yes	yes	yes	yes
Detection Name	no	yes	no	no
Detector	no	no	no	yes
Device	yes	yes	yes	yes
Disposition / File Disposition	yes	yes	yes	no
Domain	yes	yes	yes	yes
Event Subtype	no	no	no	yes
Event Type	no	yes	yes	yes
File Name	yes	yes	no	yes
File Path	no	no	no	yes
File Policy	yes	no	no	no
File Timestamp	no	no	no	yes

Field	File Event	Malware Events Detected by the Firepower System	Retrospective Events Detected by the Firepower System	Malware Events Detected by AMP for Endpoints
HTTP Response Code	yes	yes	no	no
IOC (Indication of Compromise)	no	yes	yes	yes
Message	yes	yes	no	yes
Receiving Continent	yes	yes	yes	no
Receiving Country	yes	yes	no	no
Receiving IP	yes	yes	no	yes
Receiving Port	yes	yes	no	no
Security Context	yes	yes	yes	yes
Sending Continent	yes	yes	yes	no
Sending Country	yes	yes	no	no
Sending IP	yes	yes	no	no
Sending Port	yes	yes	no	no
SHA256 / File SHA256	yes	yes	yes	yes
Size (KB) / File Size (KB)	yes	yes	no	yes
SSL Actual Action (search only)	yes	yes	no	no
SSL Certificate Information (search only)	yes	yes	no	no
SSL Failure Reason (search only)	yes	yes	no	no
SSL Status	yes	yes	no	no
SSL Subject/Issuer Country (search only)	yes	yes	no	no
File Storage / Stored (search only)	yes	yes	no	no
Threat Name	no	yes	yes	yes
Threat Score	yes	yes	no	no
Time	yes	yes	yes	yes

Field	File Event	Malware Events Detected by the Firepower System	Retrospective Events Detected by the Firepower System	Malware Events Detected by AMP for Endpoints
Type / File Type	yes	yes	no	yes
URI / File URI	yes	yes	no	no
User	yes	yes	no	yes
Web Application	yes	yes	yes	no
Web Application Category or Tag	yes	yes	yes	no

View Details About Analyzed Files

Tip To see additional options, right-click a file SHA in a table on an event page. For information, see Event Investigation Using Web-Based Resources, on page 2258.

File Composition Report

If you configure local malware analysis or dynamic analysis, the system generates a file composition report after analyzing a file. This report allows you to further analyze files and determine whether they may carry embedded malware.

The file composition report lists file properties, any objects embedded in the file, and any detected viruses. The file composition report may also list additional information specific to that file type. When the system prunes stored files, it also prunes the associated file composition report.

To view file composition information, see Using a Network File Trajectory, on page 2477.

View File Details in AMP Private Cloud

If you have deployed an AMP private cloud, you can view additional details about analyzed files in your private cloud.

For more information, see the documentation for your private cloud.

Sign in directly to your AMP private cloud console.

Threat Scores and Dynamic Analysis Summary Reports

Threat Scores

Table 328: Threat Score Ratings

Threat Score	Numeric Score	Icon
`Low`	0-24	**Low**
`Medium`	25-69	**Medium**
`High`	70-94	**High**
`Very High`	95-100	**Very High**

The Firepower Management Center caches a file's threat score for the same amount of time as the file's disposition. If the system later detects these files, it displays the cached threat scores instead of re-querying the Cisco Threat Grid cloud or an Cisco Threat Grid on-premises appliance. You can automatically assign a malware file disposition to any file with a threat score that exceeds the defined malware threshold threat score.

Dynamic Analysis Summary

If a dynamic analysis summary is available, you can click the threat score icon to view it. If multiple reports exist, this summary is based on the most recent report matching the exact threat score. If none match the exact threat score, the report with the highest threat score is displayed. If more than one report exists, you can select a threat score to view each separate report.

The summary lists each component threat comprising the threat score. Each component threat is expandable to list the AMP cloud findings, as well as any processes related to this component threat.

The process tree shows the processes that started when the Cisco Threat Grid cloud attempted to run the file. This can help identify whether a file that contains malware is attempting to access processes and system resources beyond what is expected (for example, running a Word document opens Microsoft Word, then starts Internet Explorer, then runs the Java Runtime Environment).

Each listed process contains a process identifier you can use to verify the actual process. Child nodes in the process tree represent processes started as a result of parent processes.

From the dynamic analysis summary, you can click **View Full Report** to view the full Analysis Report, detailing the AMP cloud's full analysis, including general file information, a more in-depth review of all detected processes, a breakdown of the file analysis, and other relevant information.

Viewing Dynamic Analysis Results in the Cisco Threat Grid Public Cloud

Cisco Threat Grid offers more detailed reporting on analyzed files than is available in the Firepower Management Center. If your organization has an account in the Cisco Threat Grid public cloud, you can access the Cisco Threat Grid portal directly to view additional details about files sent for analysis from your managed devices.

Before you begin

- Associate your Firepower Management Center with your Cisco Threat Grid public cloud account. See Enabling Access to Dynamic Analysis Results in the Public Cloud, on page 1476.
- License requirement: Malware
- You must be in the global domain for this task.
- You must have one of the following user roles: Admin, Access Admin, Network Admin

Step 1 Access the Cisco Threat Grid public cloud portal at the address provided in your Threat Grid documentation.

Step 2 Sign in with the account credentials that you used to create the association in the prerequisites to this task.

Step 3 View files submitted by your organization, or search for a particular file using its SHA.

If you have questions, see the Threat Grid documentation.

Using Captured File Workflows

When a managed device captures a file detected in network traffic, it logs an event.

Note If a device captures a file containing malware, the device generates two events: a file event when it detects the file, and a malware event when it identifies malware.

Use this procedure to view a list of captured files in a table and manipulate the event view depending on the information relevant to your analysis. The page you see when you access captured files differs depending on the workflow, which is simply a series of pages you can use to evaluate events by moving from a broad to a more focused view. You can also create a custom workflow that displays only the information that matches your specific needs.

If the system recaptures a file after a configuration change, such as an updated file policy, it updates existing information for that file.

For example, if you configure a file policy to capture files with a **Malware Cloud Lookup** action, the system stores the file disposition and threat score along with the file. Then, if you update your file policy, and the system recaptures the same file due to a new **Detect Files** action, the system updates the file's **Last Changed** value. However, the system does not remove the existing disposition and threat score, even though you did not perform another malware cloud lookup.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

You must be an Admin or Security Analyst user to perform this task.

Choose **Analysis** > **Files** > **Captured Files**.

Tip In the table view of events, several fields are hidden by default. To show a hidden field in an event view, expand the search constraints, then click the field name under **Disabled Columns**.

Related Topics

Captured File Fields, on page 2469
Predefined Captured File Workflows, on page 2286
Configuring Event View Settings, on page 33

Captured File Fields

The table view of captured files, which is the final page in predefined captured file workflows, and which you can add to custom workflows, includes a column for each field in the captured files table.

When searching this table keep in mind that your search results depend on the available data in the events you are searching; depending on the available data, your search constraints may not apply. For example, if a file has never been submitted for dynamic analysis, it may not have an associated threat score.

Table 329: Captured File Fields

Field	Description
Archive Inspection Status	For archive files, the status of archive inspection: • Pending indicates that the system is still inspecting the archive file and its contents. If the file passes through your system again, complete information becomes available. • Extracted indicates that the system was able to extract and inspect the archive's contents. • Failed may, in rare cases, occur if the system is unable to process an extraction. • Depth Exceeded indicates that the archive contains further nested archive files beyond the maximum allowed depth. • Encrypted indicates that the archive file's contents are encrypted and could not be inspected. • Not Inspectable indicates that the system did not extract and inspect the archive's contents. Policy rule actions, policy configuration, and corrupted files are three major reasons for this status. To view the contents of an archive file, right-click on its row in the table to bring up the context menu, then choose **View Archive Contents**.
Category	The general categories of file type, for example: Office Documents, Archive, Multimedia, Executables, PDF files, Encoded, Graphics, or System Files.

Field	Description
Detection Name	The name of the detected malware.
Disposition	The file's AMP for Networks disposition: • Malware indicates that local malware analysis identified malware, the AMP cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy. • Clean indicates that the AMP cloud categorized the file as clean, or that a user added the file to the clean list. • Unknown indicates that the system queried the AMP cloud, but the file has not been assigned a disposition; in other words, the AMP cloud has not categorized the file. • Custom Detection indicates that a user added the file to the custom detection list. • Unavailable indicates that the system could not query the AMP cloud. You may see a small percentage of events with this disposition; this is expected behavior. • N/A indicates a Detect Files or Block Files rule handled the file and the Firepower Management Center did not query the AMP cloud.
Domain	The domain where the captured file was detected. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Field	Description
Dynamic Analysis Status	One or more of the following values indicating whether the file was submitted for dynamic analysis: • Analysis Complete — file submitted for dynamic analysis that received a threat score and dynamic analysis summary report • Capacity Handled — file stored because it could not be submitted currently • Capacity Handled (Network Issue) — file stored because it could not be submitted due to a network connectivity issue • Capacity Handled (Rate Limit) — file stored because it could not be submitted due to the maximum number of submissions reached • Device Not Activated — file not submitted because the device is not activated on the on-premises Cisco Threat Grid appliance. If you see this status, contact Support. • Failure (Analysis Timeout) — file submitted for which the AMP cloud has yet to return a result • Failure (Cannot Run File) — file submitted that the AMP cloud could not run in the test environment • Failure (Network Issue) — file that did not get submitted due to a network connectivity failure • Not Sent for Analysis — file not submitted • Not Suspicious (Not Sent For Analysis) — file pre-classified as non-malware • Previously Analyzed — file with a cached threat score, indicating that it has been previously sent • Sent for Analysis — file pre-classified as malware and queued for dynamic analysis
Dynamic Analysis Status Changed	The last time the file's dynamic analysis status changed.
File Name	The most recently detected file name associated with the file's SHA-256 hash value.
Last Changed	The last time the information associated with this file was updated.
Last Sent	The time the file was most recently submitted to the AMP cloud for dynamic analysis.

Field	Description
Local Malware Analysis Status	One of the following values indicating whether the system performed local malware analysis on a file: • Analysis Complete — the system inspected the file using local malware analysis and pre-classified the file • Analysis Failed — the system attempted to inspect the file using local malware analysis and failed • Manual Request Submitted — a user submitted a file for local malware analysis • Not Analyzed — the system did not inspect the file with local malware analysis
SHA256	The SHA-256 hash value of the file, as well as a network file trajectory icon representing the most recently detected file event and file disposition. To view the network file trajectory, click the trajectory icon.
Storage Status	Indicates whether the file is stored on a managed device: • File Stored • Not Stored (Disposition Was Pending)
Threat Score	The threat score most recently associated with this file. To view the Dynamic Analysis Summary report, click the threat score icon.
Type	The type of file; for example, HTML or MSEXE.

Stored Files Download

Once a device stores a file, as long as the Firepower Management Center can communicate with that device and it has not deleted the file, you can download the file to a local host for long-term storage and analysis, and manually analyze the file. You can download a file from any associated file event, malware event, captured file view, or the file's trajectory.

Because malware is harmful, by default, you must confirm every file download. However, you can disable the confirmation in your User Preferences.

Because files with a disposition of Unknown may contain malware, when you download a file, the system first archives the file in a `.zip` package. The `.zip` file name contains the file disposition and file type, if available, and SHA-256 hash value. You can password-protect the `.zip` file to prevent accidental unpacking. You can edit or remove the default `.zip` file password in your User Preferences.

Caution Cisco strongly recommends you do **not** download malware, as it can cause adverse consequences. Exercise caution when downloading any file, as it may contain malware. Ensure you have taken any necessary precautions to secure the download destination before downloading files.

Manually Submit Files for Analysis

When you manually submit files for analysis, the system runs local analysis, then submits these files to the cloud for dynamic analysis. However, if local analysis is not enabled in a file policy, and you manually submit a file for analysis, the file will only be sent for dynamic analysis.

In addition to executable files, you can also submit file types not eligible for automatic submission, such as .swf, .jar, and others. This allows you to more quickly analyze a broad range of files, regardless of disposition, and pinpoint the exact causes of an incident.

Note The system checks the AMP cloud for updates (no more than once a day) to the list of file types eligible for dynamic analysis and the minimum and maximum file sizes you can submit.

Depending on the situation, there are two ways to submit files for analysis:

Before you begin

In order to manually submit captured files for analysis, one or more file rules must be configured to store files. For information, see File Policies and Malware Protection, on page 1459.

Step 1 To submit a single file for analysis:

a) Select one of the following:

- **Analysis > Files > File Events**
- **Analysis > Files > Malware Events**
- **Analysis > Files > Captured Files**

b) Click **Table View of <Event type or files>**.

c) Right-click a file in the table and select **Analyze File**.

Step 2 To submit multiple captured files for analysis (up to 25 at a time):

a) Select **Analysis > Files > Captured Files**

b) Select the checkbox beside each file to analyze.

c) Click **Analyze**.

Network File Trajectory

The network file trajectory feature maps how hosts transferred files, including malware files, across your network. A trajectory charts file transfer data, the disposition of the file, and if a file transfer was blocked or the file was quarantined. You can determine which hosts and users may have transferred malware, which hosts are at risk, and observe file transfer trends.

You can track the transmission of any file with a AMP cloud-assigned disposition. The system can use information related to detecting and blocking malware from both AMP for Networks and AMP for Endpoints to build the a trajectory.

Recently Detected Malware and Analyzed Trajectories

The Network File Trajectory List page displays the malware most recently detected on your network, as well as the files whose trajectory maps you have most recently viewed. From these lists, you can view when each file was most recently seen on the network, the file's SHA-256 hash value, name, type, current file disposition, contents (for archive files), and the number of events associated with the file.

The page also contains a search box that lets you locate files, either based on SHA-256 hash value or file name, or by the IP address of the host that transferred or received a file. After you locate a file, you can click the **File SHA256** value to view the detailed trajectory map.

Network File Trajectory Detailed View

You can trace a file through the network by viewing the detailed network file trajectory. Search for a file's SHA 256 value or click a **File SHA 256** link in the Network File Trajectory list to view details about that file.

The network file trajectory details page has three parts:

- Summary Information — A file's trajectory page displays summary information about the file, including file identification information; when the file was first seen and most recently seen on the network, and by what user; the number of related events and hosts associated with the file; and the file's current disposition. From this section, if the managed device stored the file, you can download it locally, submit the file for dynamic analysis, or add the file to a file list.
- Trajectory Map — A file's trajectory map visually tracks a file from the first detection on your network to the most recent. The map shows when hosts transferred or received the file, how often they transferred the file, and when the file was blocked or quarantined. Vertical lines between data points represent file transfers between hosts. Horizontal lines connecting the data points show a host's file activity over time.

  The map also shows how often file events occurred for the file and when the system assigned the file a disposition or retrospective disposition. You can select a data point in the map and highlight a path that traces back to the first instance the host transferred that file; this path also intersects with every occurrence involving the host as either sender or receiver of the file, and identifies the user involved.
- Related Events — The Events table lists event information for each data point in the map. Using the table and the map, you can pinpoint specific file events, hosts and users on the network that transferred or received this file, related events in the map, and other related events in a table constrained on selected values.

Network File Trajectory Summary Information

The following summary information appears at the top of the details page for a file that appears in the Network File Trajectory list.

Tip To view related file events, click a field value link. The first page in the File Events default workflow opens in a new window, displaying all file events that also contain the selected value.

Table 330: Network File Trajectory Summary Information Fields

Name	Description
Archive Contents	For inspected archive files, the number of files the archive contains.
Current Disposition	One of the following AMP for Networks file dispositions: • `Malware` indicates that the AMP cloud categorized the file as malware, local malware analysis identified malware, or the file's threat score exceeded the malware threshold defined in the file policy. • `Clean` indicates that the AMP cloud categorized the file as clean, or that a user added the file to the clean list. • `Unknown` indicates that the system queried the AMP cloud, but the file has not been assigned a disposition; in other words, the AMP cloud has not categorized the file. • `Custom Detection` indicates that a user added the file to the custom detection list. • `Unavailable` indicates that the system could not query the AMP cloud. You may see a small percentage of events with this disposition; this is expected behavior. • `N/A` indicates a Detect Files or Block Files rule handled the file and the Firepower Management Center did not query the AMP cloud.
Detection Name	Name of the malware detected by local malware analysis.
Event Count	The number of events seen on the network associated with the file, and the number of events displayed in the map if there are more than 250 detected events.
File Category	The general categories of file type, for example, `Office Documents` or `System Files`.

Name	Description
File Names	The names of the file associated with the event, as seen on the network. If multiple file names are associated with a SHA-256 hash value, the most recent detected file name is listed. You can expand this to view the remaining file names by clicking `more`.
File SHA256	The SHA-256 hash value of the file. The hash is displayed by default in a condensed format. To view the full hash value, hover your pointer over it. If multiple SHA-256 hash values are associated with a file name, hover your pointer over the link to view all of the hash values.
File Size (KB)	The size of the file, in kilobytes.
File Type	The file type of the file, for example, `HTML` or `MSEXE`.
First Seen	The first time AMP for Networks or AMP for Endpoints detected the file, as well as the IP address of the host that first uploaded the file and identifying information for the user involved.
Last Seen	The most recent time AMP for Networks or AMP for Endpoints detected the file, as well as the IP address of the host that last downloaded the file and identifying information for the user involved.
Parent Application	The client application accessing the malware file when detection occurred by AMP for Endpoints. These applications are **not** tied to network discovery or application control.
Seen On	The number of hosts that either sent or received the file. Because one host can upload and download a file at different times, the total number of hosts may not match the total number of senders plus the total number of receivers in the `Seen On Breakdown` field.
Seen On Breakdown	The number of hosts that sent the file, followed by the number of hosts that received the file.
Threat Name	Name of the threat associated with the detected malware by AMP for Endpoints.
Threat Score	The file's threat score.

Network File Trajectory Map and Related Events List

The file trajectory map's y-axis contains a list of all host IP addresses that have interacted with the file. The IP addresses are listed in descending order based on when the system first detected the file on that host. Each row contains all events associated with that IP address, whether a single file event, file transfer, or retrospective event. The x-axis contains the date and time the system detected each event. The timestamps are listed in

chronological order. If multiple events occurred within a minute, all are listed within the same column. You can scroll the map horizontally and vertically to view additional events and IP addresses.

The map displays up to 250 events associated with the file SHA-256 hash. If there are more than 250 events, the map displays the first 10, then truncates extra events with an **Arrow**. The map then displays the remaining 240 events.

The first page of the File Events default workflow appears in a new window with all the extra events constrained based on the file type. If malware events generated by AMP for Endpoints are not displayed, you must switch to the Malware Events table to view these.

Each data point represents an event plus the file disposition, as described in the legend below the map. For example, a Malware Block event icon combines the Malicious Disposition icon and the Block Event icon.

Malware events generated by AMP for Endpoints ("endpoint-based malware events") include one icon. A retrospective event displays an icon in the column for each host on which the file is detected. File transfer events always include two icons, one file send icon and one file receive icon, connected by a vertical line. Arrows indicate the file transfer direction from sender to receiver.

To track a file's progress through the network, you can click any data point to highlight a path that includes all data points related to the selected data point. This includes data points associated with the following types of events:

- any file transfers in which the associated IP address was either sender or receiver
- any malware events generated by AMP for Endpoints ("endpoint-based malware events") involving the associated IP address
- if another IP address was involved, all file transfers in which that associated IP address was either sender or receiver
- if another IP address was involved, any malware events generated by AMP for Endpoints ("endpoint-based malware events") involving the other IP address

All IP addresses and timestamps associated with any highlighted data point are also highlighted. The corresponding event in the Events table is also highlighted. If a path includes truncated events, the path itself is highlighted with a dotted line. Truncated events might intersect the path, but are not displayed in the map.

Using a Network File Trajectory

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Tip If your organization has deployed AMP for Endpoints, that product also has a network file trajectory feature. To pivot from FMC to AMP for Endpoints, see Work with Event Data in the AMP for Endpoints Console, on page 2479. For details about the file trajectory feature in AMP for Endpoints, see the AMP for Endpoints documentation.

Before you begin

If you are using AMP for Networks, you need the Malware license.

You must be an Admin or Security Analyst user to perform this task.

Step 1 Choose **Analysis** > **Files** > **Network File Trajectory**.

Tip You can also access a file's trajectory from the Context Explorer, dashboard, or event views with file information.

Step 2 Click a **File SHA 256** link in the list.

Step 3 Optionally, enter a complete SHA-256 hash value, the host IP address, or the name of a file you want to track into the search field, and press Enter.

Tip If only one result matches, the Network File Trajectory page for that file appears.

Step 4 In the Summary Information section, you can:

- Add a file to a file list — To add a file or remove a file from the clean list or custom detection list, click **Edit** ( ).
- Download a file — To download a file, click **Download** ( ), and if prompted, confirm you want to download the file. If the file is unavailable for download, this download file is dimmed.
- Report — Click threat score to view the Dynamic Analysis Summary report.
- Submit for dynamic analysis — Click **AMP Cloud** to submit the file for dynamic analysis. If the file is unavailable for submission or you cannot connect to the AMP cloud, this AMP cloud is dimmed.
- View archive contents — To view information about an archive file's contents, click **View** ( ).
- View file composition — To view a file's composition, click **File List**. If the system has not generated a file composition report, this file list is dimmed.
- View captured files with same threat score — Click the threat score link to view all captured files with that threat score.

Note Cisco strongly recommends you do **not** download malware, as it can cause adverse consequences. Exercise caution when downloading any file, as it may contain malware. Ensure you have taken any necessary precautions to secure the download destination before downloading files.

Step 5 On the trajectory map, you can:

- Locate the first instance — Click an IP address to locate the first time a file event occurred involving an IP address. This highlights a path to that data point, as well as any intervening file events and IP addresses related to the first file event. The corresponding event in the Events table is also highlighted. The map scrolls to that data point if not currently visible.
- Track — Click any data point to highlight a path that includes all data points related to the selected data point, tracking a file's progress through the network.
- View hidden events — Click arrow to view all events not displayed in the File Summary event view.
- View matching file events — Hover your pointer over the **Matching File Event** to view summary information for the event. If you click any event summary information link, the first page of the File Events default workflow appears in a new window with all the extra events constrained based on the file type. The File Summary event view opens in a new window, displaying all file events that match on the criteria value you clicked.

Step 6 In the Events table, you can:

- Highlight — Choose a table row to highlight a data point in the map. The map scrolls to display the selected file event if not currently visible.
- Sort — Click the column headers to sort events in ascending or descending order.

Work with Event Data in the AMP for Endpoints Console

If your organization has deployed AMP for Endpoints, you can view malware event data in the AMP for Endpoints console, and use that application's global network file trajectory tool.

Tip For information about using AMP for Endpoints and its console, see the online help in the console or other documentation available from https://www.cisco.com/c/en/us/support/security/fireamp-endpoints/tsd-products-support-series-home.html

To access the AMP for Endpoints console from the Firepower Management Center, do one of the following:

Before you begin

- The connection to AMP for Endpoints must be configured (see Integrate Firepower and AMP for Endpoints, on page 1494) and Firepower Management Center must be able to connect to the AMP cloud.
- You will need your AMP for Endpoints credentials.
- You must be an Admin user to perform this task.
- If you want to pivot from a malware event in FMC, ensure that the AMP for Endpoints contextual cross-launch options are properly enabled. See topics under Event Investigation Using Web-Based Resources, on page 2258.

Step 1 Method 1:

a) Choose **AMP** > **AMP Management**.
b) Click the cloud name in the table.

Step 2 Method 2:

a) Navigate to a malware event in a table under **Analysis > Files**.
b) Right-click a file SHA and choose an AMP for Endpoints option.

History for File and Malware Events and Network File Trajectory

Feature	Version	Details
Unique identifier for connection event in syslogs	6.4.0.4	The following syslog fields collectively uniquely identify a connection event and appear in syslogs for file and malware events: DeviceUUID, First Packet Time, Connection Instance ID, and Connection Counter.
Ability to send file and malware events via syslog	6.4	Field descriptions in this chapter specify the fields included in syslog messages. For configuration information, see Configuration Locations for Syslogs for File and Malware Events, on page 2268.

CHAPTER 123

Using Host Profiles

The following topics describe how to use host profiles:

Requirements and Prerequisites for Host Profiles

Model Support

Any.

Supported Domains

Any

User Roles

- Admin
- Security Analyst

Host Profiles

A host profile provides a complete view of all the information the system has gathered about a single host. To access a host profile:

- navigate from any network map view.
- navigate from any event view that includes the IP addresses of hosts on monitored networks.

Host profiles provide basic information about detected hosts or devices, such as the host name or MAC addresses. Depending on your licenses and system configuration, host profiles can also provide you with the following information:

- the operating system running on a host
- the servers running on a host
- the clients and web applications running on a host
- the protocols running on a host
- the indications of compromise (IOC) tags on a host
- the VLAN tags on a host
- the last twenty-four hours of user activity on your network
- the compliance white violations associated with a host
- the most recent malware events for a host
- the vulnerabilities associated with a host
- the Nmap scan results for a host

Host attributes are also listed in the profile. You can use host attributes to classify hosts in ways that are important to your network environment. For example, you can:

- assign a host attribute that indicates the building where the host is located
- use the *host criticality* attribute to designate the business criticality of a given host and tailor correlation policies and alerts based on host criticality

From a host profile, you can view the existing host attributes applied to that host and modify the host attribute values.

If you use adaptive profile updates as part of a passive intrusion prevention deployment, you can tailor the way the system processes traffic so it best fits the type of operating system on the host and the servers and clients the host is running.

Optionally, you can perform an Nmap scan from the host profile to augment the server and operating system information in your host profile. The Nmap scanner actively probes the host to obtain information about the operating system and servers running on the host. The results of the scan are added to the list of operating system and server identities for the host.

Related Topics

Viewing Host Profiles, on page 2483

Host Profile Limitations

Unavailable Hosts

A host profile may not be available for every host on your network. Possible reasons include:

- The host was deleted from the network map because it timed out.
- You have reached your host limit.
- The host resides in a network segment that is not monitored by the network discovery policy.

Unavailable Information

The information displayed in a host profile may vary according to the type of host and the information available about the host.

For example:

- If your system detects a host using a non-IP-based protocol like STP, SNAP, or IPX, the host is added to the network map as a MAC host and much less information is available than for an IP host.
- The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

Viewing Host Profiles

You have two choices:

- On any network map, drill down to the IP address of the host whose profile you want to view.
- On any event view, click **Host Profile** or **Compromised Host** next to the IP address of the host whose profile you want to view.

Basic Host Information in the Host Profile

Each host profile provides basic information about a detected host or other device.

Descriptions of each of the basic host profile fields follow.

Domain

The domain associated with the host.

IP Addresses

All IP addresses (both IPv4 and IPv6) associated with the host. The system detects IP addresses associated with hosts and, where supported, groups multiple IP addresses used by the same host. IPv6 hosts often have at least two IPv6 addresses (local-only and globally routable), and may also have IPv4 addresses. IPv4-only hosts may have multiple IPv4 addresses.

The host profile lists all detected IP addresses associated with that host. Where available, routable host IP addresses also include a flag icon and country code indicating the geolocation data associated with that address.

Note that only the first three addresses are shown by default. Click **show all** to show all addresses for a host.

Hostname

The fully qualified domain name of the host, if known.

NetBIOS Name

The NetBIOS name of the host, if available. Microsoft Windows hosts, as well as Macintosh, Linux, or other platforms configured to use NetBIOS, can have a NetBIOS name. For example, Linux hosts configured as Samba servers have NetBIOS names.

Device (Hops)

Either:

- the reporting device for the network where the host resides, as defined in the network discovery policy, or
- the device that processed the NetFlow data that added the host to the network map

The number of network hops between the device that detected the host and the host itself follows the device name, in parentheses. If multiple devices can see the host, the reporting device is displayed in bold.

If this field is blank, either:

- the host was added to the network map by a device that is not explicitly monitoring the network where the host resides, as defined in the network discovery policy, or
- the host was added using the host input feature and has not also been detected by the Firepower System.

MAC Addresses (TTL)

The host's detected MAC address or addresses and associated NIC vendors, with the NIC's hardware vendor and current time-to-live (TTL) value in parentheses.

If multiple devices detected the host, the Firepower Management Center displays all MAC addresses and TTL values associated with the host, regardless of which device reported them.

If the MAC address is displayed in bold font, the MAC address is the actual/true/primary MAC address of the host, definitively tied to the IP address by detection through ARP and DHCP traffic.

MAC addresses that are not displayed in bold font are secondary addresses, which cannot be definitively associated with the IP address of the host. For example, since the Firepower device can obtain MAC addresses only for hosts on its own network segments, if traffic originates from a network segment to which the Firepower device is not directly connected, the observed MAC address (i.e. the router MAC address) will be displayed as a secondary MAC address for the host.

Host Type

The type of device that the system detected: host, mobile device, jailbroken mobile device, router, bridge, NAT device, or load balancer.

The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their type (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge
- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers
- The methods the system uses to distinguish mobile devices include:
- analysis of User-Agent strings in HTTP traffic from the mobile device's mobile browser
- monitoring of HTTP traffic of specific mobile applications

If a device is not identified as a network device or a mobile device, it is categorized as a host.

Last Seen

The date and time that any of a host's IP addresses was last detected.

Current User

The user most recently logged into this host.

Note that a non-authoritative user logging into a host only registers as the current user on the host if the existing current user is not an authoritative user.

View

Links to views of connection, discovery, malware, and intrusion event data, using the default workflow for that event type and constrained to show events related to the host; where possible, these events include all IP addresses associated with the host.

Operating Systems in the Host Profile

The system passively detects the identity of the operating system running on a host by analyzing the network and application stack in traffic generated by the host or by analyzing host data reported by the User Agent. The system also collates operating system information from other sources, such as the Nmap scanner or application data imported through the host input feature. The system considers the priority assigned to each identity source when determining which identity to use. By default, user input has the highest priority, followed by application or scanner sources, followed by the discovered identity.

Sometimes the system supplies a general operating system definition rather than a specific one because the traffic and other identity sources do not provide sufficient information for a more focused identity. The system collates information from the sources to use the most detailed definition possible.

Because the operating system affects the vulnerabilities list for the host and the event impact correlation for events targeting the host, you may want to manually supply more specific operating system information. In addition, you can indicate that fixes have been applied to the operating system, such as service packs and updates, and invalidate any vulnerabilities addressed by the fixes.

For example, if the system identifies a host's operating system as Microsoft Windows 2003, but you know that the host is actually running Microsoft Windows XP Professional with Service Pack 2, you can set the operating system identity accordingly. Setting a more specific operating system identity refines the list of vulnerabilities for the host, so your impact correlation for that host is more focused and accurate.

If the system detects operating system information for a host and that information conflicts with a current operating system identity that was supplied by an active source, an identity conflict occurs. When an identity conflict is in effect, the system uses both identities for vulnerabilities and impact correlation.

You can configure the network discovery policy to add discovery data to the network map for hosts monitored by NetFlow exporters. However, there is no operating system data available for these hosts, unless you set the use the host input feature to set the operating system identity.

If a host is running an operating system that violates a compliance white list in an activated network discovery policy, the Firepower Management Center marks the operating system information with the white list **Violation**. In addition, if a jailbroken mobile device violates an active white list, the icon appears next to the operating system for the device.

You can set a custom display string for the host's operating system identity. That display string is then used in the host profile.

Note Changing the operating system information for a host may change its compliance with a compliance white list.

In the host profile for a network device, the label for the Operating Systems section changes to Systems and an additional Hardware column appears. If a value for a hardware platform is listed under Systems, that system represents a mobile device or devices detected behind the network device. Note that mobile devices may or may not have hardware platform information, but hardware platform information is never detected for systems that are not mobile devices.

Descriptions of the operating system information fields displayed in the host profile follow.

Hardware

The hardware platform for a mobile device.

OS Vendor/Vendor

The operating system vendor.

OS Product/Product

One of the following values:

- the operating system determined most likely to be running on the host, based on the identity data collected from all sources
- `Pending` if the system has not yet identified an operating system and no other identity data is available
- `unknown` if the system cannot identify the operating system and no other identity data is available for the operating system

Note If the host's operating system is not one the system is capable of detecting, see Identifying Host Operating Systems, on page 1938:

OS Version/Version

The operating system version. If a host is a jailbroken mobile device, `Jailbroken` is indicated in parentheses after the version.

Source

One of the following values:

- User: user_name
- Application: app_name
- Scanner: scanner_type (Nmap or other scanner)
- Firepower

The system may reconcile data from multiple sources to determine the identity of an operating system.

Viewing Operating System Identities

You can view the specific operating system identities discovered or added for a host. The system uses source prioritization to determine the current identity for the host. In the list of identities, the current identity is highlighted by boldface text.

Note that the **View** is only available if multiple operating system identities exist for the host.

Step 1 Click **View** in the **Operating System** or **Operating System Conflicts** section of a host profile.

Step 2 View the information described in Operating Systems in the Host Profile, on page 2485.

Step 3 Optionally, click **Delete** ( ) next to any operating system identity.

/firepower/fmc/fmc_config_guide/discovery-host-profiles/t_editing_server_identities.xml

Note You cannot delete Cisco-detected operating system identities.

This system removes the identity from the Operating System Identity Information pop-up window and, if applicable, updates the current identity for the operating system in the host profile.

Setting the Current Operating System Identity

You can set the current operating system identity for a host using the Firepower System web interface. Setting the identity through the web interface overrides all other identity sources so that identity is used for vulnerability assessment and impact correlation. However, if the system detects a conflicting operating system identity for the host after you edit the operating system, an operating system conflict occurs. Both operating systems are then considered current until you resolve the conflict.

Step 1 Click **Edit** in the **Operating System** section of a host profile.

Step 2 You have several options:

- Choose **Current Definition** from the **OS Definition** drop-down list to confirm the current operating system identity through host input, then skip to step 6.
- Choose a variation on the current operating system identity from the **OS Definition** drop-down list, then skip to step 6.
- Choose **User-Defined** from the **OS Definition** drop-down list, then continue with step 3.

Step 3 Optionally, choose **Use Custom Display String** and modify the custom strings you want to display in the **Vendor String**, **Product String**, and **Version String** fields.

Step 4 Optionally, to change to an operating system from a different vendor, choose from the **Vendor** and **Product** drop-down lists.

Step 5 Optionally, to configure the operating system product release level, choose from the **Major**, **Minor**, **Revision**, **Build**, **Patch**, and **Extension** drop-down lists.

Step 6 Optionally, if you want to indicate that fixes for the operating system have been applied, click **Configure Fixes**.

Step 7 Choose the applicable fixes in the drop-down list, and click **Add**.

Step 8 Optionally, add the relevant patches and extensions using the **Patch** and **Extension** drop-down lists.

Step 9 Click **Finish**.

Related Topics

Operating System Identity Conflicts, on page 2488

Operating System Identity Conflicts

An operating system identity conflict occurs when a new identity detected by the system conflicts with the current identity, if that identity was provided by an active source, such as a scanner, application, or user.

The list of operating system identities in conflict displays in bold in the host profile.

You can resolve an identity conflict and set the current operating system identity for a host through the system web interface. Setting the identity through the web interface overrides all other identity sources so that identity is used for vulnerability assessment and impact correlation.

Related Topics

Configuring Network Discovery Identity Conflict Resolution, on page 2082

Making a Conflicting Operating System Identity Current

Step 1 Navigate to the **Operating System** section of a host profile.

Step 2 You have two choices:

- Click **Make Current** next to the operating system identity you want to set as the operating system for the host.
- If the identity that you *do not* want as the current identity came from an active source, delete the unwanted identity.

Resolving an Operating System Identity Conflict

Step 1 Click **Resolve** in the **Operating System Conflicts** section of a host profile.

Step 2 You have the following choices:

- Choose **Current Definition** from the **OS Definition** drop-down list to confirm the current operating system identity through host input, then skip to step 6.
- Choose a variation on one of the conflicting operating system identities from the **OS Definition** drop-down list, then skip to step 6.
- Choose **User-Defined** from the **OS Definition** drop-down list, then continue with step 3.

Step 3 Optionally, choose **Use Custom Display String** and enter the custom strings you want to display in the **Vendor String**, **Product String**, and **Version String** fields.

Step 4 Optionally, to change to an operating system from a different vendor, choose from the **Vendor** and **Product** drop-down lists.

Step 5 Optionally, to configure the operating system product release level, choose from the **Major**, **Minor**, **Revision**, **Build, Patch,** and **Extension** drop-down lists.

Step 6 Optionally, if you want to indicate that fixes for the operating system have been applied, click **Configure Fixes**.

Step 7 Add the fixes you have applied to the fixes list.

Step 8 Click **Finish**.

Configuring Network Discovery Identity Conflict Resolution, on page 2082

Servers in the Host Profile

The Servers Section of the host profile lists servers either detected on hosts on your monitored network, added from exported NetFlow records, or added through an active source like a scanner or the host input feature.

The list can include up to 100 servers per host. After that limit is reached, new server information from any source, whether active or passive, is discarded until you delete a server from the host or a server times out.

If you scan a host using Nmap, Nmap adds the results of previously undetected servers running on open TCP ports to the Servers list. If you perform an Nmap scan or import Nmap results, an expandable Scan Results section also appears in the host profile, listing the server information detected on the host by the Nmap scan. In addition, if the host is deleted from the network map, the Nmap scan results for that server for the host are discarded.

Note The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

The process for working with servers in the host profile differs depending on how you access the profile:

- If you access the host profile by drilling down through the network map, the details for that server appear with the server name highlighted in bold. If you want to view the details for any other server on the host, click **View** ( ) next to that server name.

- If you access the host profile in any other way, expand the Servers section and click **View** ( ) next to the server whose details you want to see.

Note If the host is running a server that violates a compliance white list in an activated correlation policy, the Firepower Management Center marks the non-compliant server with the white list **Violation**.

Descriptions of the columns in the Servers list follow.

Protocol

The name of the protocol the server uses.

Port

The port where the server runs.

Application Protocol

One of:

- the name of the application protocol
- `pending` if the system cannot positively or negatively identify the application protocol for one of several reasons
- `unknown` if the system cannot identify the application protocol based on known application protocol fingerprints, or if the server was added through host input by adding a vulnerability with port information without adding a corresponding server

When you hover the mouse on an application protocol name, the tags display.

Vendor and Version

The vendor and version identified by the Firepower System, Nmap, or another active source, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Application Detector Fundamentals, on page 1976

Server Details in the Host Profile

The Firepower Management Center lists up to 16 passively detected identities per server. Passive detection sources include network discovery data and NetFlow records. A server can have multiple passive identities if the system detects multiple vendors or versions of that server. For example, a load balancer between your managed device and your web server farm may cause your system to identify multiple passive identities for HTTP if your web servers are not running the same version of the server software. Note that the Firepower Management Center does not limit the number of server identities from active sources such as user input, scanners, or other applications.

The Firepower Management Center displays the current identity in bold. The system uses the current identity of a server for multiple purposes, including assigning vulnerabilities to a host, impact assessment, evaluating correlation rules written against host profile qualifications and compliance white lists, and so on.

The server detail may also display updated sub-server information known about the selected server.

The server detail may also display the server banner, which appears below the server details when you view a server from the host profile. Server banners provide additional information about a server that may help you identify the server. The system cannot identify or detect a misidentified server when an attacker purposely alters the server banner string. The server banner displays the first 256 bytes of the first packet detected for the server. It is collected only once, the first time the server is detected by the system. Banner content is listed in two columns, with a hexadecimal representation on the left and a corresponding ASCII representation on the right.

Note To view server banners, you must enable the **Capture Banners** check box in the network discovery policy. This option is disabled by default.

The server details section of the host profile includes the following information:

Protocol

The name of the protocol the server uses.

Port

The port where the server runs.

Hits

The number of times the server was detected by a Firepower System managed device or an Nmap scanner. The number of hits is 0 for servers imported through host input, unless the system detects traffic for that server.

Last Used

The time and date the server was last detected. The last used time for host input data reflects the initial data import time unless the system detects new traffic for that server. Scanner and application data imported through the host input feature times out according to settings in the Firepower Management Center configuration, but user input through the FMC web interface does not time out.

Application Protocol

The name of the application protocol used by the server, if known.

Vendor

The server vendor. This field does not appear if the vendor is unknown.

Version

The server version. This field does not appear if the version is unknown.

Source

One of the following values:

- User: user_name
- Application: app_name

- Scanner: scanner_type (Nmap or other scanner)
- `Firepower`, `Firepower Port Match`, or `Firepower Pattern Match` for applications detected by the Firepower System
- `NetFlow` for servers added to the network map from NetFlow records

The system may reconcile data from multiple sources to determine the identity of a server.

Related Topics

Current Identities for Applications and Operating Systems, on page 1919

Viewing Server Details

In a host profile, click **View** ( ) next to a server in the **Servers** section.

Editing Server Identities

You can manually update the identity settings for a server on a host and configure any fixes that you have applied to the host to remove the vulnerabilities addressed by the fixes. You can also delete server identities.

Deleting an identity does not delete the server, even if you delete the only identity. Deleting an identity does remove the identity from the Server Detail pop-up window and, if applicable, updates the current identity for the server in the host profile.

You cannot edit or delete server identities added by a Cisco-managed device.

Step 1 Navigate to the **Servers** section of a host profile.

Step 2 Click **View** to open the Server Detail pop-up window.

Step 3 To delete a server identity, click **Delete** ( ) next to the server identity you want to remove.

Step 4 To modify a server identity, click **Edit** ( ) next to the server in the servers list.

Step 5 You have two choices:

- Choose the current definition from the **Select Server Type** drop-down list.
- Choose the type of server from the **Select Server Type** drop-down list.

Step 6 Optionally, to only list vendors and products for that server type, choose the **Restrict by Server Type** check box.

Step 7 Optionally, to customize the name and version of the server, choose the **Use Custom Display String**, and enter a **Vendor String** and **Version String**.

Step 8 In the **Product Mappings** section, choose the operating system, product, and versions you want to use.

Example:

For example, if you want the server to map to Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 9 If you want to indicate that fixes for the server have been applied, click **Configure Fixes**, and add the patches you want to apply for that server to the fixes list.

Step 10 Click **Finish**.

Resolving Server Identity Conflicts

A server identity conflict occurs when an active source, such as an application or scanner, adds identity data for a server to a host, after which the system detects traffic for that port that indicates a conflicting server identity.

Step 1 In a host profile, navigate to the **Servers** section.

Step 2 Click resolve next to a server.

Step 3 Choose the type of server from the **Select Server Type** drop-down list.

Step 4 Optionally, to only list vendors and products for that server type, choose the **Restrict by Server Type** check box.

Step 5 Optionally, to customize the name and version of the server, choose **Use Custom Display String**, and enter a **Vendor String** and **Version String**.

Step 6 In the **Product Mappings** section, choose the operating system, product, and versions you want to use.

Example:

For example, if you want the server to map to Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 7 If you want to indicate that fixes for the server have been applied, click **Configure Fixes**, and add the patches you want to apply for that server to the fixes list.

Step 8 Click **Finish**.

Related Topics

Configuring Network Discovery Identity Conflict Resolution, on page 2082

Web Applications in the Host Profile

The Web Application section of the host profile displays the clients and web applications that the system identifies as running on the hosts on your network. The system can identify client and web application information from both passive and active detection sources, although the information for hosts added from NetFlow records is limited.

Details in this section include the product and version of the detected applications on a host, any available client or web application information, and the time that the application was last detected in use.

The section lists up to 16 clients running on the host. After that limit is reached, new client information from any source, whether active or passive, is discarded until you delete a client application from the host or the system deletes the client from the host profile due to inactivity (the client times out).

Additionally, for each detected web browser, the system displays the first 100 web applications accessed. After that limit is reached, new web applications associated with that browser from any source, whether active or passive, are discarded until either:

- the web browser client application times out, or
- you delete application information associated with a web application from the host profile

If the host is running an application that violates a compliance white list in an activated correlation policy, the Firepower Management Center marks the non-compliant application with the white list **Violation**.

Tip To analyze the connection events associated with a particular application on the host, click **Logging** ( ) next to the application. The first page of your preferred workflow for connection events appears, showing connection events constrained by the type, product, and version of the application, as well as the IP address(es) of the host. If you do not have a preferred workflow for connection events, you must select one.

Descriptions of the application information that appears in a host profile follow.

Application Protocol

Displays the application protocol used by the application (HTTP browser, DNS client, and so on).

Client

Client information derived from payload if identified by the Firepower System, captured by Nmap, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Version

Displays the version of the client.

Web Application

For web browsers, the content detected by the system in the http traffic. Web application information indicates the specific type of content (for example, WMV or QuickTime) identified by the Firepower System, captured by Nmap, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Deleting Web Applications from the Host Profile

You can delete an application from a host profile to remove applications that you know are not running on the host. Note that deleting an application from a host may bring the host into compliance with a compliance white list.

Note If the system detects the application again, it re-adds it to the network map and the host profile.

Step 1 In a host profile, navigate to the **Applications** section.

Step 2 Click **Delete** ( ) next to the application you want to delete.

Host Protocols in the Host Profile

Each host profile contains information about the protocols detected in the network traffic associated with the host. This information includes:

Protocol

The name of a protocol used by the host.

Layer

The network layer where the protocol runs (`Network` or `Transport`).

If a protocol displaying in the host profile violates a compliance white list in an activated correlation policy, the Firepower Management Center marks the non-compliant protocol with the white list **violation**.

If the host profile lists protocols that you know are not running on the host, you can delete those protocols. Deleting a protocol from a host may bring the host into compliance with a compliance white list.

Note If the system detects the protocol again, it re-adds it to the network map and the host profile.

Deleting a Protocol From the Host Profile

Step 1 Navigate to the **Protocols** section of a host profile.

Step 2 Click **Delete** () next to the protocol you want to delete.

Indications of Compromise in the Host Profile

The Firepower System correlates various types of data (intrusion events, Security Intelligence, connection events, and file or malware events) to determine whether a host on your monitored network is likely to be compromised by malicious means. Certain combinations and frequencies of event data trigger indications of compromise (IOC) tags on affected hosts.

The Indications of Compromise section of the host profile displays all indication of compromise tags for a host.

To configure the system to tag indications of compromise, see Enabling Indications of Compromise Rules, on page 2084.

For more information about working with indications of compromise, see Indications of Compromise Data, on page 2529 and the subtopics under that topic.

Related Topics

Indications of Compromise, on page 2084

VLAN Tags in the Host Profile

The VLAN Tag section of the host profile appears if the host is a member of a Virtual LAN (VLAN).

Physical network equipment often uses VLANs to create logical network segments from different network blocks. The system detects 802.1q VLAN tags and displays the following information for each:

- **VLAN ID** identifies the VLAN where the host is a member. This can be any integer between zero and 4095 for 802.1q VLANs.
- **Type** identifies the encapsulated packet containing the VLAN tag, which can be either Ethernet or Token Ring.
- **Priority** identifies the priority in the VLAN tag, which can be any integer from zero to 7, where 7 is the highest priority.

If VLAN tags are nested within the packet, the system processes and the Firepower Management Center displays the innermost VLAN tag. The system collects and displays VLAN tag information only for MAC addresses that it identifies through ARP and DHCP traffic.

VLAN tag information can be useful, for example, if you have a VLAN composed entirely of printers and the system detects a Microsoft Windows 2000 operating system in that VLAN. VLAN information also helps the system generate more accurate network maps.

User History in the Host Profile

The user history portion of the host profile provides a graphic representation of the last twenty-four hours of user activity. A typical user logs off in the evening and may share the host resource with another user. Periodic login requests, such as those made to check email, are indicated by short regular bars. A list of user identities is provided with bar graphs to indicate when the user login was detected. Note that for non-authoritative logins, the bar graph is gray.

Note that the system does associate a non-authoritative user login to a host with an IP address of that host, so the user does appear in the host's user history. However, if an authoritative user login is detected for the same host, the user associated with the authoritative user login takes over the association with the host IP address, and new non-authoritative user logins do not disrupt that user association with the host IP address. If you configure capture of failed logins in the network discovery policy, the list includes users that failed to log into the host.

Host Attributes in the Host Profile

You can use *host attributes* to classify hosts in ways that are important to your network environment. Three types of attributes are present in the Firepower System:

- *predefined host attributes*
- *compliance white list host attributes*
- *user-defined host attributes*

After you set a predefined host attribute or create a user-defined host attribute, you must assign a host attribute value.

Note Host attributes can be defined at any domain level. You can assign host attributes created in current and ancestor domains.

Predefined Host Attributes

The Firepower Management Center provides two predefined host attributes:

Host Criticality

Use this attribute to designate the business criticality of a given host and to tailor correlation responses to host criticality. For example, if you consider your organization's mail servers more critical to your business than a typical user workstation, you can assign a value of High to your mail servers and other business-critical devices and Medium or Low to other hosts. You can then create a correlation policy that launches different alerts based on the criticality of an affected host.

Notes

Use this host-specific attribute to record information about the host that you want other analysts to view. For example, if you have a computer on the network that has an older, unpatched version of an operating system that you use for testing, you can use the Notes feature to indicate that the system is intentionally unpatched.

White List Host Attributes

Each compliance white list that you create automatically creates a host attribute with the same name as the white list. Possible values for white list host attributes are:

- Compliant — Identifies hosts that are compliant with the white list.
- Non-Compliant — Identifies hosts that violate the white list.
- Not Evaluated — Identifies hosts that are not valid targets of the white list or have not been evaluated for any reason.

You cannot edit the value of a white list host attribute or delete a white list host attribute.

User-Defined Host Attributes

If you want to identify hosts using criteria that differs from those used in the predefined host attributes or compliance white list host attributes, you can create user-defined host attributes. For example, you can:

- Assign physical location identifiers to hosts, such as a facility code, city, or room number.
- Assign a Responsible Party Identifier that indicates which system administrator is responsible for a given host. You can then craft correlation rules and policies to send alerts to the correct system administrator when problems related to a host are detected.
- Automatically assign values to hosts from a predefined list based on the hosts' IP addresses. This feature can be useful to assign values to new hosts when they appear on your network for the first time.

User-defined host attributes appear in the host profile page, where you can assign values on a per-host basis. You can also:

- Use the attributes in correlation policies and searches.
- View the attributes on the host attribute table view of events and generate reports based on them.

User-defined host attributes can be one of the following types:

Text

Allows you to manually assign a text string to a host.

Integer

Allows you to specify the first and last number of a range of positive integers, then manually assign one of these numbers to a host.

List

Allows you to create a list of string values, then manually assign one of the values to a host. You can also automatically assign values to hosts based on the host's IP addresses.

If you auto-assign values based on one IP address of a host with multiple IP addresses, those values will apply across all addresses associated with that host. Keep this in mind when you view the Host Attributes table.

When automatically assigning list values, consider using network objects rather than literal IP addresses. This approach can improve maintainability, particularly in a multidomain deployment where using override-enabled objects allows descendant domain administrators to tailor ancestor configurations to their local environments. In a multidomain deployment, be careful when defining auto-assigned lists at ancestor domain levels to avoid matching unintended hosts when the descendant domains use overlapping IP addresses.

URL

Allows you to manually assign a URL value to a host.

Deleting a user-defined host attribute removes it from every host profile where it is used.

Creating Text- or URL-Based Host Attributes

Step 1 Choose **Analysis** > **Hosts** > **Host Attributes**.

Step 2 Click **Host Attribute Management**.

Step 3 Click **Create Attribute**.

Step 4 Enter a **Name**.

Step 5 Choose the **Type** of attribute that you want to create as described in User-Defined Host Attributes, on page 2497

Step 6 Click **Save**.

Creating Integer-Based Host Attributes

When you define an integer-based host attribute, you must specify the range of numbers that the attribute accepts.

Step 1 Choose **Analysis** > **Hosts** > **Host Attributes**.
Step 2 Click **Host Attribute Management**.
Step 3 Click **Create Attribute**.
Step 4 Enter a **Name**.
Step 5 Choose the **Type** of attribute that you want to create as described in User-Defined Host Attributes, on page 2497.
Step 6 In the **Min** field, enter the minimum integer value that can be assigned to a host.
Step 7 In the **Max** field, enter the maximum integer value that can be assigned to a host.
Step 8 Click **Save**.

Creating List-Based Host Attributes

When you define a list-based host attribute, you must supply each of the values for the list. These values can contain alphanumeric characters, spaces, and symbols.

Step 1 Choose **Analysis** > **Hosts** > **Host Attributes**.
Step 2 Click **Host Attribute Management**.
Step 3 Click **Create Attribute**.
Step 4 Enter a **Name**.
Step 5 Choose the **Type** of attribute that you want to create as described in User-Defined Host Attributes, on page 2497.
Step 6 To add a value to the list, click **Add Value**.
Step 7 In the **Name** field, enter the first value you want to add.
Step 8 Optionally, to auto-assign the attribute value you just added to your hosts, click **Add Networks**.
Step 9 Choose the value you added from the **Value** drop-down list.
Step 10 In the **IP Address** and **Netmask** fields, enter the IP address and network mask (IPv4) that represent the IP address block where you want to auto-assign this value.
Step 11 Repeat steps 6 through 10 to add additional values to the list and assign them automatically to new hosts that fall within an IP address block.
Step 12 Click **Save**.

Setting Host Attribute Values

You can set values for predefined and user-defined host attributes. You cannot set values for compliance white list host attributes generated by the system.

Step 1 Open the host profile you want to modify.

Step 2 In the **Attributes** section, click **Edit Attributes**.

Step 3 Update attribute as desired.

Step 4 Click **Save**.

White List Violations in the Host Profile

A *compliance white list* (or *white list*) is a set of criteria that allows you to specify the operating systems, application protocols, clients, web applications, and protocols that are allowed to run on a specific subnet.

If you add a white list to an active correlation policy, when the system detects that a host is violating the white list, the Firepower Management Center logs a white list event—which is a special kind of correlation event—to the database. Each of these white list events is associated with a *white list violation*, which indicates how and why a particular host is violating the white list. If a host violates one or more white lists, you can view these violations in its host profile in two ways.

First, the host profile lists all of the individual white list violations associated with the host.

Descriptions of the white list violation information in the host profile follow.

Type

The type of the violation, that is, whether the violation occurred as a result of a non-compliant operating system, application, server, or protocol.

Reason

The specific reason for the violation. For example, if you have a white list that allows only Microsoft Windows hosts, the host profile displays the current operating system running on the host (such as `Linux Linux 2.4, 2.6`)

White List

The name of the white list associated with the violation.

Second, in the sections associated with operating systems, applications, protocols, and servers, the Firepower Management Center marks non-compliant elements with the white list **Violation**. For example, for a white list that allows only Microsoft Windows hosts, the host profile displays the white list violation icon next to the operating system information for that host.

Note You can use a host's profile to create a shared host profile for compliance white lists.

Creating Shared White List Host Profiles

Shared host profiles for compliance white lists specify which operating systems, application protocols, clients, web applications, and protocols are allowed to run on target hosts across multiple white lists. That is, if you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile.

You can use a host profile of any host with a known IP address to create a shared host profile that your compliance white lists can use. However, note that you cannot create a shared host profile based on an individual host's host profile if the system has not yet identified the operating system of the host.

Step 1 In a host profile, click **Generate White List Profile**.

Step 2 Modify and save the shared host profile according to your specific needs.

Related Topics

Building White List Host Profiles, on page 2100

Malware Detections in the Host Profile

The Most Recent Malware Detections section lists the most recent malware events where the host sent or received a malware file, up to 100 events. The host profile lists both network-based malware events (those generated by AMP for Networks) and endpoint-based malware events (those generated by AMP for Endpoints).

If the host is involved in a file event where the file is then retrospectively identified as malware, the original events where the file was transmitted appear in the malware detections list after the malware identification occurs. When a file identified as malware is retrospectively determined not to be malware, the malware events related to that file no longer appear in the list. For example, if a file has a disposition of `Malware` and that disposition changes to `Clean`, the event for that file is removed from the malware detections list on the host profile.

When viewing malware detections in the host profile, you can view malware events for that host by clicking the **Malware**.

Description of the columns in the Most Recent Malware Detections sections of the host profile follow.

Time

The date and time the event was generated.

For an event where the file was retrospectively identified as malware, note that this is the time of the original event, not the time when the malware was identified.

Host Role

The host's role in the transmission of detected malware, either sender or receiver. Note that for malware events generated by AMP for Endpoints ("endpoint-based malware events"), the host is always the receiver.

Threat Name

The name of the detected malware.

File Name

The name of the malware file.

File Type

The type of file; for example, `PDF` or `MSEXE`.

Vulnerabilities in the Host Profile

The Vulnerabilities sections of the host profile list the vulnerabilities that affect that host. These vulnerabilities are based on the operating system, servers, and applications that the system detected on the host.

If there is an identity conflict for either the identity of the host's operating system or one of the application protocols on the host, the system lists vulnerabilities for both identities until the conflict is resolved.

Because no operating system information is available for hosts added to the network map from NetFlow data, the system cannot assign Vulnerable (impact level 1: red) impact levels for intrusion events involving those hosts. In such cases, use the host input feature to manually set the operating system identity for the hosts.

Server vendor and version information is often not included in traffic. By default, the system does not map the associated vulnerabilities for the sending and receiving hosts of such traffic. However, you can configure the system to map vulnerabilities for specific application protocols that do not have vendor or version information.

If you use the host input feature to add third-party vulnerability information for the hosts on your network, additional Vulnerabilities sections appear. For example, if you import vulnerabilities from a QualysGuard Scanner, host profiles on your include a QualysGuard Vulnerabilities section. For third-party vulnerabilities, the information in the corresponding Vulnerabilities section in the host profile is limited to the information that you provided when you imported the vulnerability data using the host input feature.

You can associate third-party vulnerabilities with operating systems and application protocols, but not clients. For information on importing third-party vulnerabilities, see the *Firepower System Host Input API Guide*.

Descriptions of the columns in the Vulnerabilities sections of the host profile follow.

Name

The name of the vulnerability.

Remote

Indicates whether the vulnerability can be remotely exploited. If this column is blank, the vulnerability definition does not include this information.

Component

The name of the operating system, application protocol, or client associated with the vulnerability.

Port

A port number, if the vulnerability is associated with an application protocol running on a specific port.

Related Topics

Vulnerability Data Fields, on page 2541
Vulnerability Deactivation, on page 2542

Downloading Patches for Vulnerabilities

You can download patches to mitigate the vulnerabilities discovered on the hosts on your network.

Step 1 Access the host profile of a host for which you want to download a patch.
Step 2 Expand the **Vulnerabilities** section.
Step 3 Click the name of the vulnerability you want to patch.
Step 4 Expand the **Fixes** section to display the list of patches for the vulnerability.
Step 5 Click **Download** next to the patch you want to download.
Step 6 Download the patch and apply it to your affected systems.

Deactivating Vulnerabilities for Individual Hosts

You can use the host vulnerability editor to deactivate vulnerabilities on a host-by-host basis. When you deactivate a vulnerability for a host, it is still used for impact correlations for that host, but the impact level is automatically reduced one level.

Step 1 Navigate to the **Vulnerabilities** section of a host profile.
Step 2 Click **Edit Vulnerabilities**.
Step 3 Choose the vulnerability from the **Valid Vulnerabilities** list, and click the down arrow to move it to the **Invalid Vulnerabilities** list.

Tip You can click and drag to choose multiple adjacent vulnerabilities; you can also double-click any vulnerability to move it from list to list.

Step 4 Click **Save**.

What to do next

- Optionally, activate the vulnerability for the host by moving it from the **Invalid Vulnerabilities** list to the **Valid Vulnerabilities** list.

Related Topics

Deactivating Individual Vulnerabilities, on page 2503
Deactivating Multiple Vulnerabilities, on page 2544

Deactivating Individual Vulnerabilities

If you deactivate a vulnerability in a host profile, it deactivates it for all hosts in your network map. However, you can reactivate it at any time.

In a multidomain deployment, deactivating a vulnerability in an ancestor domain deactivates it in all descendant domains. Leaf domains can activate or deactivate a vulnerability for their devices if the vulnerability is activated in the ancestor domain.

Step 1 Access the vulnerability detail:

- In an affected host profile, expand the **Vulnerabilities** section, and click the name of the vulnerability you want to enable or disable.
- In the predefined workflow, choose **Analysis** > **Hosts** > **Vulnerabilities**, and click **View** ( ) next to the vulnerability you want to enable or disable.

Step 2 Choose **Disabled** from the **Impact Qualification** drop-down list.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Confirm that you want to change the **Impact Qualification** value for all hosts on the network map.

Step 4 Click **Done**.

What to do next

- Optionally, activate the vulnerability by choosing **Enabled** from the **Impact Qualification** drop-down list while performing the steps above.

Operating System Identity Conflicts, on page 2488

Scan Results in the Host Profile

When you scan a host using Nmap, or when you import results from an Nmap scan, those results appear in the host profile for any hosts included in the scan.

The information that Nmap collects about the host operating system and any servers running on open unfiltered ports is added directly into the Operating System and Servers sections of the host profile, respectively. In addition, Nmap adds a list of the scan results for that host in the Scan Results section. Note that the scan must find open ports on the host for Scan Results section to appear in the profile.

Each result indicates the source of the information, the number and type of the scanned port, the name of the server running on the port, and any additional information detected by Nmap, such as the state of the port or the vendor name for the server. If you scan for UDP ports, servers detected on those ports only appear in the Scan Results section.

Note that you can run an Nmap scan from the host profile.

Scanning a Host from the Host Profile

You can perform a Nmap scan against a host from the host profile. After the scan completes, server and operating system information for that host are updated in the host profile. Any additional scan results are added to the Scan Results section of the host profile.

Caution Nmap-supplied server and operating system data remains static until you run another Nmap scan or override it with higher priority host input. If you plan to scan a host using Nmap, regularly schedule scans.

Before you begin

- Add an Nmap scan instance; see Adding an Nmap Scan Instance, on page 1965.

Step 1 In the host profile, click **Scan Host**.

Step 2 Click **Scan** next to the scan remediation you want to use to scan the host.

The system scans the host and adds the results to the host profile.

CHAPTER 124

Working with Discovery Events

The following topics describe how to work with discovery events:

Requirements and Prerequisites for Discovery Events

Model Support

Any.

Supported Domains

Any

User Roles

- Admin
- Security Analyst

Discovery and Identity Data in Discovery Events

The system generates tables of events that represent the changes detected in your monitored network. You can use these tables to review the user activity on your network and determine how to respond. The *network discovery* and *identity* policies specify the kinds of data you want to collect, the network segments you want to monitor, and the specific hardware interfaces you want to use to do it.

You can use discovery and identity event tables to identify threats associated with hosts, applications, and users on your network. The system provides a set of predefined workflows that you can use to analyze the

events that your system generates. You can also create custom workflows that display only the information that matches your specific needs.

To collect and store network discovery and identity data for analysis, you must configure network discovery and identity policies. After you configure an identity policy, you must invoke it in your access control policy and deploy it to the devices you want to use to monitor traffic.

Your network discovery policy provides host, application, and non-authoritative user data. Your identity policy provides authoritative user data.

The following discovery event tables are located under the Analysis > Hosts and Analysis > Users menus.

Discovery Event Table	Populated With Discovery Data?	Populated With Identity Data?
Hosts	Yes	No
Host Indications of Compromise	Yes	No
Applications	Yes	No
Application Details	Yes	No
Servers	Yes	No
Host Attributes	Yes	No
Discovery Events	Yes	Yes
User Indications of Compromise	Yes	Yes
Active Sessions	Yes	Yes
User Activity	Yes	Yes
Users	Yes	Yes
Vulnerabilities	Yes	No
Third-Party Vulnerabilities	Yes	No

Viewing Discovery Event Statistics

The Discovery Statistics page displays a summary of the hosts, events, protocols, application protocols, and operating systems detected by the system.

The page lists statistics for the last hour and the total accumulated statistics. You can choose to view statistics for a particular device, or all devices. You can also view events that match the entries on the page by clicking the event, server, operating system, or operating system vendor listed within the summary.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Overview** > **Summary** > **Discovery Statistics**.

Step 2 From the **Select Device** list, choose the device whose statistics you want to view. Optionally, choose **All** to view statistics for all devices managed by the Firepower Management Center.

Step 3 You have the following options:

- In the Statistics Summary, view general statistics as described in The Statistics Summary Section, on page 2509.
- In the Event Breakdown, click the type of event you want to view. If no events appear, you may need to adjust the time range as described in Changing the Time Window, on page 2314.
- In the Protocol Breakdown, view the protocols currently in use by detected hosts.
- In the Application Protocol Breakdown, click the name of the application protocol you want to view.
- In the OS Breakdown, click the **OS Name** or **OS Vendor**.

Related Topics

The Event Breakdown Section, on page 2510
The Protocol Breakdown Section, on page 2510
The Application Protocol Breakdown Section, on page 2510
The OS Breakdown Section, on page 2511

The Statistics Summary Section

Descriptions of the rows of the Statistics Summary section follow.

Total Events

Total number of discovery events stored on the Firepower Management Center.

Total Events Last Hour

Total number of discovery events generated in the last hour.

Total Events Last Day

Total number of discovery events generated in the last day.

Total Application Protocols

Total number of application protocols from servers running on detected hosts.

Total IP Hosts

Total number of detected hosts identified by unique IP address.

Total MAC Hosts

Total number of detected hosts not identified by IP address.

Note that the Total MAC Hosts statistic remains the same whether you are viewing discovery statistics for all devices or for a specific device. This is so because managed devices discover hosts based on their IP addresses.

This statistic gives the total of all hosts that are identified by other means and is independent of a given managed device.

Total Routers

Total number of detected nodes identified as routers.

Total Bridges

Total number of detected nodes identified as bridges.

Host Limit Usage

Total percentage of the host limit currently in use. The host limit is defined by the model of your Firepower Management Center. Note that the host limit usage only appears if you are viewing statistics for all managed devices.

Note If the host limit is reached and a host is deleted, the host will not reappear on the network map you purge discovery data.

Last Event Received

The date and time that the most recent discovery event occurred.

Last Connection Received

The date and time that the most recent connection was completed.

The Event Breakdown Section

The Event Breakdown section lists a count of each type of discovery event and host input event that occurred within the last hour, as well as a count of the total number of each event type stored in the database.

You can also use the Event Breakdown section to view details on discovery and host input events.

Related Topics

Discovery and Host Input Events, on page 2514

The Protocol Breakdown Section

The Protocol Breakdown section lists the protocols currently in use by detected hosts. It displays each detected protocol name, its “layer” in the protocol stack, and the total number of hosts that communicate using the protocol.

The Application Protocol Breakdown Section

The Application Protocol Breakdown section lists the application protocols that are currently in use by detected hosts. It lists the protocol name, the total number of hosts running the application protocol in the past hour, and the total number of hosts that have been detected running the protocol at any point.

You can also use the Application Protocol Breakdown section to view details on servers using the detected protocols.

Related Topics

Server Data, on page 2533

The OS Breakdown Section

The OS Breakdown section lists the operating systems currently running on the monitored network, along with their vendors and the total number of hosts running each operating system.

A value of `unknown` for the operating system name or version means that the operating system or its version does not match any of the system's fingerprints. A value of `pending` means that the system has not yet gathered enough information to identify the operating system or its version.

You can use the OS Breakdown section to view details on the detected operating systems.

Related Topics

Host Data, on page 2521

Viewing Discovery Performance Graphs

You can generate graphs that display performance statistics for managed devices with discovery events.

New data is accumulated for statistics graphs every five minutes. Therefore, if you reload a graph quickly, the data may not change until the next five-minute increment occurs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

Edit the applicable network discovery policy to include applications, hosts, and users. (This may impact system performance.) See Configuring Network Discovery Rules, on page 2072 and Actions and Discovered Assets, on page 2073.

You must be an Admin or Maintenance user to perform this task.

Step 1 Choose **Overview** > **Summary** > **Discovery Performance**.

Step 2 From the **Select Device** list, choose the Firepower Management Center or managed devices you want to include.

Step 3 From the **Select Graph(s)** list, choose the type of graph you want to create as described in Discovery Performance Graph Types, on page 2511.

Step 4 From the **Select Time Range** list, choose the time range you would like to use for the graph.

Step 5 Click **Graph** to graph the selected statistics.

Discovery Performance Graph Types

Descriptions of the available graph types follow.

Processed Events/Sec

Displays a graph that represents the number of events that the Data Correlator processes per second

Processed Connections/Sec

Displays a graph that represents the number of connections that the Data Correlator processes per second

Generated Events/Sec

Displays a graph that represents the number of events that the system generates per second

Mbits/Sec

Displays a graph that represents the number of megabits of traffic that are analyzed by the discovery process per second

Avg Bytes/Packet

Displays a graph that represents the average number of bytes included in each packet analyzed by the discovery process

K Packets/Sec

Displays a graph that represents the number of packets analyzed by the discovery process per second, in thousands

Using Discovery and Identity Workflows

The Firepower Management Center provides a set of event workflows that you can use to analyze the discovery and identity data that is generated for your network. The workflows are, along with the network map, a key source of information about your network assets.

The Firepower Management Center provides predefined workflows for discovery and identity data, detected hosts and their host attributes, servers, applications, application details, vulnerabilities, user activities, and users. You can also create custom workflows.

Step 1 To access a predefined workflow:

- Discovery and Host Input Data — See Viewing Discovery and Host Input Events, on page 2520.
- Host Data — See Viewing Host Data, on page 2522.
- Host Attributes Data — See Viewing Host Attributes, on page 2527.
- Host or User Indications of Compromise Data — See View and Work with Indications of Compromise Data, on page 2529.
- Server Data — See Viewing Server Data, on page 2533.
- Application Data — See Viewing Application Data, on page 2536.
- Application Detail Data — See Viewing Application Detail Data, on page 2538.

- Active Session Data — See Viewing Active Session Data, on page 2553.
- User Data — See Viewing User Data, on page 2556.
- User Activity Data — See Viewing User Activity Data, on page 2558.
- Network Map — See Viewing Network Maps, on page 2240.

Step 2 To access a custom workflow, choose **Analysis** > **Advanced** > **Custom Workflows**.

Step 3 To access a workflow based on a custom table, choose **Analysis** > **Advanced** > **Custom Tables**.

Step 4 Perform any of the following actions, which are common to all of the pages accessed in the network discovery workflows:

- Constrain Columns — To constrain the columns that display, click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

  Tip To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, click the expand arrow to expand the search constraints, then click the column name under Disabled Columns.

- Delete — To delete some or all items in the current constrained view, check the check boxes next to items you want to delete and click **Delete**, or click **Delete All**. These items remain deleted until the system's discovery function is restarted, when they may be detected again.

  Caution Before you delete a non-VPN session on the Analysis > Users > Active Sessions page, verify that the session is actually closed. After you delete the active session, an applicable policy will not be able to detect the session on the device, and therefore the session will not be monitored or blocked even if the policy was configured to perform those actions.

  Note For more information about VPN sessions on the Analysis > Users > Active Sessions page, see Viewing Remote Access VPN Current Users.

  Note You **cannot** delete Cisco (as opposed to third-party) vulnerabilities; you can, however, mark them reviewed.

- Drill Down — To drill down to the next page in the workflow, see Using Drill-Down Pages, on page 2301.
- Navigate Current Page — To navigate within the current workflow page, see Workflow Page Navigation Tools, on page 2299.
- Navigate within a Workflow — To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- Navigate to Other Workflows — To navigate to other event views to examine associated events, see Inter-Workflow Navigation, on page 2319.
- Sort Data — To sort data in a workflow, click the column title. Click the column title again to reverse the sort order.
- View Host Profile — To view the host profile for an IP address, click **Host Profile** or, for hosts with active indications of compromise (IOC) tags, the **Compromised Host** that appears next to the IP address.
- View User Profile — To view user identity information, click the user icon that appears next to the **User Identity**, or for users associated with IOCs,**Red User**.

Discovery and Host Input Events

The system generates discovery events that communicate the details of changes in your monitored network segments. *New* events are generated for newly discovered network features, and change events are generated for any change in previously identified network assets.

During its initial network discovery phase, the system generates new events for each host and any TCP or UDP servers discovered running on each host. Optionally, you can configure the system to use exported NetFlow records to generate these new host and server events.

In addition, the system generates new events for each network, transport, and application protocol running on each discovered host. You can disable detection of application protocols in discovery rules configured to monitor NetFlow exporters, but not in discovery rules configured to monitor Firepower System managed devices. If you enable host or user discovery in non-NetFlow discovery rules, applications are automatically discovered.

After the initial network mapping is complete, the system continuously records network changes by generating change events. Change events are generated whenever the configuration of a previously discovered asset changes.

When a discovery event is generated, it is logged to the database. You can use the Firepower Management Center web interface to view, search, and delete discovery events. You can also use discovery events in correlation rules. Based on the type of discovery event generated as well as other criteria that you specify, you can build correlation rules that, when used in a correlation policy, launch remediations and syslog, SNMP, and email alert responses when network traffic meets your criteria.

You can add data to the network map using the host input feature. You can add, modify, or delete operating system information, which causes the system to stop updating that information for that host. You can also manually add, modify, or delete application protocols, clients, servers, and host attributes or modify vulnerability information. When you do this, the system generates host input events.

Discovery Event Types

You can configure the types of discovery events the system logs in your network discovery policy. When you view the discovery events table, the event type is listed in the **Event** column. Descriptions of the discovery event types follow.

Additional MAC Detected for Host

This event is generated when the system detects a new MAC address for a previously discovered host.

This event is often generated when the system detects hosts passing traffic through a router. While each host has a different IP address, they all appear to have the MAC address associated with the router. When the system detects the actual MAC address associated with the IP address, it displays the MAC address in bold text within the host profile and displays an “ARP/DHCP detected” message within the event description in the event view.

Client Timeout

This event is generated when the system drops a client from the database due to inactivity.

Client Update

This event is generated when the system detects a payload (that is, a specific type of content, such as audio, video, or webmail) in HTTP traffic.

DHCP: IP Address Changed

This event is generated when the system detects that a host IP address has changed due to DHCP address assignment.

DHCP: IP Address Reassigned

This event is generated when a host is reusing an IP address; that is, when a host obtains an IP address formerly used by another physical host due to DHCP IP address assignment.

Hops Change

This event is generated when the system detects a change in the number of network hops between a host and the device that detects the host. This may happen if:

- The device sees host traffic through different routers and is able to make a better determination of the host's location.
- The device detects an ARP transmission from the host, indicating that the host is on a local segment.

Host Deleted: Host Limit Reached

This event is generated when the host limit on the Firepower Management Center is exceeded and a monitored host is deleted from the network map.

Host Dropped: Host Limit Reached

This event is generated when the host limit on the Firepower Management Center is reached and a new host is dropped. Compare this with the previous event where old hosts are deleted from the network map when the host limit is reached.

To drop new hosts when the host limit is reached, go to **Policies** > **Network Discovery** > **Advanced** and set **When Host Limit Reached** to **Drop hosts**.

Host IOC Set

This event is generated when an IOC (Indications of Compromise) is set for a host and generates an alert.

Host Timeout

This event is generated when a host is dropped from the network map because the host has not produced traffic within the interval defined in the network discovery policy. Note that individual host IP addresses and MAC addresses time out individually; a host does not disappear from the network map unless all of its associated addresses have timed out.

If you change the networks you want to monitor in your network discovery policy, you may want to manually delete old hosts from the network map so that they do not count against your host limit.

Host Type Changed to Network Device

This event is generated when the system detects that a detected host is actually a network device.

Identity Conflict

This event is generated when the system detects a new server or operating system identity that conflicts with a current active identity for that server or operating system.

If you want to resolve identity conflicts by rescanning the host to obtain newer active identity data, you can use Identity Conflict events to trigger an Nmap remediation.

Identity Timeout

This event is generated when server or operating system identity data from an active source times out.

If you want to refresh identity data by rescanning the host to obtain newer active identity data, you can use Identity Conflict events to trigger an Nmap remediation.

MAC Information Change

This event is generated when the system detects a change in the information associated with a specific MAC address or TTL value.

This event often occurs when the system detects hosts passing traffic through a router. While each host hnetas a different IP address, they will all appear to have the MAC address associated with the router. When the system detects the actual MAC address associated with the IP address, it displays the MAC address in bold text within the host profile and displays an "ARP/DHCP detected" message within the event description in the event view. The TTL may change because the traffic may pass through different routers or if the system detects the actual MAC address of the host.

NETBIOS Name Change

This event is generated when the system detects a change to a host's NetBIOS name. This event will only be generated for hosts using the NetBIOS protocol.

New Client

This event is generated when the system detects a new client.

Note To collect and store client data for analysis, make sure that you enable application detection in your discovery rules in the network discovery policy.

New Host

This event is generated when the system detects a new host running on the network.

This event can also be generated when a device processes NetFlow data that involves a new host. To generate an event in this case, configure the network discovery rule that manages NetFlow data to discover hosts.

New Network Protocol

This event is generated when the system detects that a host is communicating with a new network protocol (IP, ARP, and so on).

New OS

This event is generated when the system either detects a new operating system for a host, or a change in a host's operating system.

New TCP Port

This event is generated when the system detects a new TCP server port (for example, a port used by SMTP or web services) active on a host. This event is not used to identify the application protocol or the server associated with it; that information is transmitted in the TCP Server Information Update event.

This event can also be generated when a device processes NetFlow data involving a server on your monitored networks that does not already exist in the network map. To generate an event in this case, configure the network discovery rule that manages NetFlow data to discover applications.

New Transport Protocol

This event is generated when the system detects that a host is communicating with a new transport protocol, such as TCP or UDP.

New UDP Port

This event is generated when the system detects a new UDP server port running on a host.

This event can also be generated when a device processes NetFlow data involving a server on your monitored networks that does not already exist in the network map. To generate an event in this case, configure the network discovery rule that manages NetFlow data to discover applications.

TCP Port Closed

This event is generated when the system detects that a TCP port has closed on a host.

TCP Port Timeout

This event is generated when the system has not detected activity from a TCP port within the interval defined in the system's network discovery policy.

TCP Server Information Update

This event is generated when the system detects a change in a discovered TCP server running on a host.

This event may be generated if a TCP server is upgraded.

UDP Port Closed

This event is generated when the system detects that a UDP port has closed on a host.

UDP Port Timeout

This event is generated when the system has not detected activity from a UDP port within the interval defined in the network discovery policy.

UDP Server Information Update

This event is generated when the system detects a change in a discovered UDP server running on a host.

This event may be generated if a UDP server is upgraded.

VLAN Tag Information Update

This event is generated when the system detects a change in the VLAN tag attributed to a host.

Related Topics

Host Input Event Types, on page 2518
Network Discovery Data Storage Settings, on page 2085
Application and Operating System Identity Conflicts, on page 1921
Network Discovery Identity Conflict Settings, on page 2082

Host Input Event Types

When you view a table of discovery events, the event type is listed in the **Event** column.

Contrast host input events, which are generated when a user takes a specific action (such as manually adding a host), with discovery events, which are generated when the system itself detects a change in your monitored network (such as detecting traffic from a previously undetected host).

You can configure the types of host input events that the system logs by modifying your network discovery policy.

If you understand the information the different types of host input events provide, you can more effectively determine which events you want to log and alert on, and how to use these alerts in correlation policies. In addition, knowing the names of the event types can help you craft more effective event searches. Descriptions of the different types of host input events follow.

Add Client

This event is generated when a user adds a client.

Add Host

This event is generated when a user adds a host.

Add Protocol

This event is generated when a user adds a protocol.

Add Scan Result

This event is generated when the system adds the results of an Nmap scan to a host.

Add Port

This event is generated when a user adds a server port.

Delete Client

This event is generated when a user deletes a client from the system.

Delete Host/Network

This event is generated when a user deletes an IP address or subnet from the system.

Delete Protocol

This event is generated when a user deletes a protocol from the system.

Delete Port

This event is generated when a user deletes a server port or group of server ports from the system.

Host Attribute Add

This event is generated when a user creates a new host attribute.

Host Attribute Delete

This event is generated when a user deletes a user-defined host attribute.

Host Attribute Delete Value

This event is generated when a user deletes a value assigned to a host attribute.

Host Attribute Set Value

This event is generated when a user sets a host attribute value for a host.

Host Attribute Update

This event is generated when a user changes the definition of a user-defined host attribute.

Set Host Criticality

This event is generated when a user sets or modifies the host criticality value for a host.

Set Operating System Definition

This event is generated when a user sets the operating system for a host.

Set Server Definition

This event is generated when a user sets the vendor and version definitions for a server.

Set Vulnerability Impact Qualification

This event is generated when a vulnerability impact qualification is set.

When a vulnerability is disabled at a global level from being used for impact qualifications, or when a vulnerability is enabled at a global level, this event is generated.

Vulnerability Set Invalid

This event is generated when a user invalidates (or reviews) a vulnerability or vulnerabilities.

Vulnerability Set Valid

This event is generated when a user validates a vulnerability that was previously marked as invalid.

Related Topics

Discovery Event Types, on page 2514

Viewing Discovery and Host Input Events

Discovery events workflows allow you to view data from both discovery events and host input events. You can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access events differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of discovery events and a terminating host view page. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Choose **Analysis** > **Hosts** > **Discovery Events**.

Step 2 You have the following options:

- Adjust the time range as described in Changing the Time Window, on page 2314.

  Note Events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Discovery Event Fields, on page 2520.

Related Topics

Using Discovery and Identity Workflows, on page 2512

Discovery Event Fields

Descriptions of the fields that can be viewed and searched in the discovery events table follow.

Time

The time that the system generated the event.

Event

The discovery event type or host input event type.

IP Address

The IP address associated with the host involved in the event.

User

The last user to log into the host involved in the event before the event was generated. If only non-authoritative users log in after an authoritative user, the authoritative user remains the current user for the host unless another authoritative user logs in.

MAC Address

The MAC address of the NIC used by the network traffic that triggered the discovery event. This MAC address can be either the actual MAC address of the host involved in the event, or the MAC address of a network device that the traffic passed through.

MAC Vendor

The MAC hardware vendor of the NIC used by the network traffic that triggered the discovery event.

When searching this field, enter **`virtual_mac_vendor`** to match events that involve virtual hosts.

Port

The port used by the traffic that triggered the event, if applicable.

Description

The text description of the event.

Domain

The domain of the device that discovered the host. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Device

The name of the managed device that generated the event. For new host and new server events based on NetFlow data, this is the managed device that processed the data.

Related Topics

Event Searches, on page 2323

Host Data

The system generates an event when it detects a host and collects information about it to build the host profile. You can use the Firepower Management Center web interface to view, search, and delete hosts.

While viewing hosts, you can create traffic profiles and compliance white lists based on selected hosts. You can also assign host attributes, including host criticality values (which designate business criticality) to groups of hosts. You can then use these criticality values, white lists, and traffic profiles within correlation rules and policies.

The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

Related Topics

Differences between NetFlow and Managed Device Data, on page 1923

Viewing Host Data

You can use the Firepower Management Center to view a table of hosts that the system has detected. Then, you can manipulate the view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access hosts differs depending on the workflow you use. Both predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the host data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Hosts**.
- If you are using a custom workflow that does not include the table view of hosts, click **(switch workflow)**, then choose **Hosts**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Host Data Fields, on page 2522.
- Right-click an item in the table to see options. (Not every column offers options.)
- Assign a host attribute to specific hosts; see Setting Host Attributes for Selected Hosts, on page 2528.
- Create traffic profiles for specific hosts, see Creating a Traffic Profile for Selected Hosts, on page 2526.
- Create a compliance white list based on specific hosts, see Creating a Compliance White List Based on Selected Hosts, on page 2526.

Host Data Fields

When the system discovers a host, it collects data about that host. That data can include the host's IP addresses, the operating system it is running, and more. You can view some of that information in the table view of hosts.

Descriptions of the fields that can be viewed and searched in the hosts table follow below.

Last Seen

The date and time any of the host's IP addresses was last detected by the system. The Last Seen value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system generates a new host event for any of the host's IP addresses.

For hosts with operating system data updated using the host input feature, the Last Seen value indicates the date and time when the data was originally added.

IP Address

The IP addresses associated with the host.

MAC Address

The host's detected MAC address of the NIC.

The MAC Address field appears in the Table View of Hosts, which you can find in the Hosts workflow. You can also add the MAC Address field to:

- custom tables that include fields from the Hosts table
- drill-down pages in custom workflows based on the Hosts table

MAC Vendor

The host's detected MAC hardware vendor of the NIC.

The MAC Vendor field appears in the Table View of Hosts, which you can find in the Hosts workflow. You can also add the MAC Vendor field to:

- custom tables that include fields from the Hosts table
- drill-down pages in custom workflows based on the Hosts table

When searching this field, enter `virtual_mac_vendor` to match events that involve virtual hosts.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Host Criticality

The user-specified criticality value assigned to the host.

NetBIOS Name

The NetBIOS name of the host. Only hosts running the NetBIOS protocol will have a NetBIOS name.

VLAN ID

VLAN ID used by the host.

Hops

The number of network hops from the device that detected the host to the host.

Host Type

The type of host. Can be any of the following: host, mobile device, jailbroken mobile device, router, bridge, NAT device, and load balancer.

The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their type (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge

- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers

If a device is not identified as a network device, it is categorized as a host.

When searching this field, enter `!host` to search for all network devices.

Hardware

The hardware platform for a mobile device.

OS

One of the following:

- The operating system (name, vendor, and version) either detected on the host or updated using Nmap or the host input feature
- `unknown` if the operating system does not match any known fingerprint
- `pending` if the system has not yet gathered enough information to identify the operating system

If the system detects multiple identities, it displays those identities in a comma-separated list.

This field appears when you invoke the hosts event view from the Custom Analysis widget on the dashboard. It is also a field option in custom tables based on the Hosts table.

When searching this field, enter `n/a` to include hosts where the operating system has not yet been identified.

OS Conflict

This field is search only.

OS Vendor

One of the following:

- The vendor of the operating system detected on the host or updated using Nmap or the host input feature
- `unknown` if the operating system does not match any known fingerprint
- `pending` if the system has not yet gathered enough information to identify the operating system

If the system detects multiple vendors, it displays those vendors in a comma-separated list.

When searching this field, enter `n/a` to include hosts where the operating system has not yet been identified.

OS Name

One of the following:

- The operating system detected on the host or updated using Nmap or the host input feature
- `unknown` if the operating system does not match any known fingerprint
- `pending` if the system has not yet gathered enough information to identify the operating system

If the system detects multiple names, it displays those names in a comma-separated list.

When searching this field, enter `n/a` to include hosts where the operating system has not yet been identified.

OS Version

One of the following:

- The version of the operating system detected on the host or updated using Nmap or the host input feature
- `unknown` if the operating system does not match any known fingerprint
- `pending` if the system has not yet gathered enough information to identify the operating system

If the system detects multiple versions, it displays those versions in a comma-separated list.

When searching this field, enter `n/a` to include hosts where the operating system has not yet been identified.

Source Type

The type of source used to establish the host's operating system identity:

- User: user_name
- Application: app_name
- Scanner: scanner_type (Nmap or scanner added through network discovery configuration)
- `Firepower` for operating systems detected by the system

The system may reconcile data from multiple sources to determine the identity of an operating system.

Confidence

One of the following:

- the percentage of confidence that the system has in the identity of the operating system running on the host, for hosts detected by the system
- 100%, for operating systems identified by an active source, such as the host input feature or Nmap scanner
- `unknown`, for hosts for which the system cannot determine an operating system identity, and for hosts added to the network map based on NetFlow data

When searching this field, enter `n/a` to include hosts added to the network map based on NetFlow data.

Notes

The user-defined content of the Notes host attribute.

Domain

The domain associated with the host. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Device

Either the managed device that detected the traffic or the device that processed NetFlow or host input data.

If this field is blank, either of the following conditions is true:

- The host was added to the network map by a device that is not explicitly monitoring the network where the host resides, as defined in the network discovery policy.
- The host was added using the host input feature and has not also been detected by the system.

Count

The number of events that match the information that appears in each row. This field appears only after you apply a constraint that creates two or more identical rows.

Operating System Identity Conflicts, on page 2488

Creating a Traffic Profile for Selected Hosts

A traffic profile is a profile of the traffic on your network, based on connection data collected over a timespan that you specify. After you create a traffic profile, you can detect abnormal network traffic by evaluating new traffic against your profile, which presumably represents normal network traffic.

You can use the Hosts page to create a traffic profile for a group of hosts that you specify. The traffic profile will be based on connections detected where one of the hosts you specify is the initiating host. Use the sort and search features to isolate the hosts for which you want to create a profile.

Before you begin

You must be an Admin user to perform this task.

Step 1 On a table view in the hosts workflow, check the check boxes next to the hosts for which you want to create a traffic profile.

Step 2 At the bottom of the page, click **Create Traffic Profile**.

Step 3 Modify and save the traffic profile according to your specific needs.

Related Topics

Introduction to Traffic Profiles, on page 2143

Creating a Compliance White List Based on Selected Hosts

Compliance white lists allow you to specify which operating systems, clients, and network, transport, or application protocols are allowed on your network.

You can use the Hosts page to create a compliance white list based on the host profiles of a group of hosts that you specify. Use the sort and search features to isolate the hosts that you want to use to create a white list.

Before you begin

You must be an Admin user to perform this task.

Step 1 On a table view in the hosts workflow, check the check boxes next to the hosts for which you want to create a white list.

Step 2 At the bottom of the page, click **CreateWhite List**.

Step 3 Modify and save the white list according to your specific needs.

Related Topics

Introduction to Compliance White Lists, on page 2093

Host Attribute Data

The Firepower System collects information about the hosts it detects and uses that information to build host profiles. However, there may be additional information about the hosts on your network that you want to provide to your analysts. You can add notes to a host profile, set the business criticality of a host, or provide any other information that you choose. Each piece of information is called a *host attribute*.

You can use host attributes in host profile qualifications, which constrain the data you collect while building a traffic profile, and also can limit the conditions under which you want to trigger a correlation rule. You can also set attribute values in response to a correlation rule.

Related Topics

Viewing Host Attributes, on page 2527
Configuring Set Attribute Remediations, on page 2163

Viewing Host Attributes

You can use the Firepower Management Center to view a table of hosts detected by the system, along with their host attributes. Then, you can manipulate the view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access host attributes differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of host attributes that lists all detected hosts and their attributes, and terminates in a host view page, which contains a host profile for every host that meets your constraints.

You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the host attributes data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Host Attributes**.
- If you are using a custom workflow that does not include the table view of host attributes, click **(switch workflow)**, then choose **Attributes**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Host Attribute Data Fields, on page 2528.

- Assign a host attribute to specific hosts; see Setting Host Attributes for Selected Hosts, on page 2528.

Host Attribute Data Fields

Note that the host attributes table does not display hosts identified only by MAC addresses.

Descriptions of the fields that can be viewed and searched in the host attributes table follow.

IP Address

The IP addresses associated with a host.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Host Criticality

The user-assigned importance of a host to your enterprise. You can use the host criticality in correlation rules and policies to tailor policy violations and their responses to the importance of a host involved in an event. You can assign a host criticality of low, medium, high, or none.

Notes

Information about the host that you want other analysts to view.

Any user-defined host attribute, including those for compliance white lists

The value of the user-defined host attribute. The host attributes table contains a field for each user-defined host attribute.

Domain

The domain associated with the host. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Event Searches, on page 2323

Setting Host Attributes for Selected Hosts

You can configure predefined and user-defined host attributes from a host workflow.

Step 1 In a host workflow, check the check boxes next to the hosts to which you want to add a host attribute.

Tip Use the sort and search features to isolate the hosts to which you want to assign particular attributes.

Step 2 At the bottom of the page, click **Set Attributes**.

Step 3 Optionally, set the host criticality for the hosts you selected. You can choose **None**, **Low**, **Medium**, or **High**.

Step 4 Optionally, add notes to the host profiles of the hosts you selected in the text box.

Step 5 Optionally, set any user-defined host attributes you have configured.

Step 6 Click **Save**.

Indications of Compromise Data

The Firepower System correlates various types of data (intrusion events, Security Intelligence, connection events, and file or malware events) to determine whether a host on your monitored network is likely to be compromised by malicious means. Certain combinations and frequencies of event data trigger indications of compromise (IOC) tags on affected hosts. The IP addresses of these hosts appear in event views with a **Red Compromised Host icon** .

When a host is identified as potentially compromised, the user associated with that compromise is also tagged. These users appear in event views with a **Red User icon**.

If a file containing malware is seen again within 300 seconds of being tagged as an IOC, another IOC is not generated. If the same file is seen more than 300 seconds later, a new IOC will be generated.

To configure the system to tag events as indications of compromise, see Enabling Indications of Compromise Rules, on page 2084.

Related Topics

Enabling Indications of Compromise Rules, on page 2084

View and Work with Indications of Compromise Data

You can use the Firepower Management Center to view tables showing Indications of Compromise (IOC). Manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see depends on the workflow you use. The predefined IOC workflows terminate in a profile view, which contains a host or user profile for every host or user that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs.

Before you begin

- For your system to detect and tag indications of compromise (IOC), you must activate the IOC feature in the network discovery policy and enable at least one IOC rule. See Enabling Indications of Compromise Rules, on page 2084.
- Users must be identified in an active Identity policy.

Step 1 Determine which location in the web interface presents information that meets your needs.

You can use the following locations to view or work with Indication of Compromise data:

- Event Viewer (under the Analysis menu) — Connection, Security Intelligence, intrusion, malware, and IOC discovery event views indicate whether an event triggered an IOC. Note that malware events generated by AMP for Endpoints that trigger IOC rules have the event type `AMP IOC` and appear with an event subtype that specifies the compromise.
- Dashboard — In the dashboard, Threats of the Summary Dashboard displays, by default, IOC tags by host and by user. The Custom Analysis widget offers presets based on IOC data.
- Context Explorer — The Indications of Compromise section of the Context Explorer displays graphs of hosts by IOC category and IOC categories by host.
- Network Map page — The Indications of Compromise under Analysis > Hosts > Network Map groups potentially compromised hosts on your network by type of compromise and IP address.
- Network File Trajectory details page — The details pages for files listed under Analysis > Files > Network File Trajectory let you track indications of compromise on your network.
- Host Indications of Compromise page — The Host Indications of Compromise page under the Analysis > Hosts menu lists monitored hosts, grouped by IOC tag. Use the workflows on this page to drill down into your data.
- User Indications of Compromise page — The User Indications of Compromise page under the Analysis > Users menu lists users associated with potential IOC events, grouped by IOC tag. Use the workflows on this page to drill down into your data.
- Host Profile page — The host profile for a potentially compromised host displays all IOC tags associated with that host, and lets you resolve IOC tags and configure IOC rule states.
- User Profile page — The user profile for a user associated with a potential IOC event displays all IOC tags associated with that user, and lets you resolve IOC tags and configure IOC rule states. (The user profile is labeled "User Identity" in the Firepower Management Center web interface.)

Step 2 If applicable, do one of the following and use the rest of the steps in this procedure:

Option	Description
To research IOCs on hosts:	• If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Indications of Compromise**. • If you are using a custom workflow that does not include the Host IOC table view, click **(switch workflow)**, then choose **Host Indications of Compromise** .
To research IOCs associated with users:	• If you are using the predefined workflow, choose **Analysis > Users > Indications of Compromise**. • If you are using a custom workflow that does not include the User IOC table view, click **(switch workflow)**, then choose **User Indications of Compromise**.

Step 3 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.

- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Indications of Compromise Data Fields, on page 2531.
- On a Host Indications of Compromise page: View the host profile for a compromised host by clicking **Compromised Host** in the **IP Address** column.
- On a User Indications of Compromise page: View the user profile associated with a compromise by clicking **Red User** in the **User** column.
- Mark IOC events resolved so they no longer appear in the list. To do so, check the check boxes next to the IOC events you want to modify, then click **Mark Resolved**.
- View details of events that triggered the IOC by clicking **View** () in the **First Seen** or **Last Seen** columns.
- See more options: Right-click a value in the table.

Indications of Compromise Data Fields

The following are the fields in Host or User IOC (indication of compromise) tables. Not every IOC-related table includes all fields.

IP Address (When viewing Host IOC data)

The IP address associated with the host that triggered the IOC.

User (When viewing User IOC data)

The username, realm, and authentication source of the user associated with the event that triggered the IOC.

Category

Brief description of the type of compromise indicated, such as `Malware Executed` or `Impact 1 Attack`.

Event Type

Identifier associated with a specific IOC, referring to the event that triggered it.

Description

Description of the impact on the potentially compromised host, such as `This host may be under remote control` or `Malware has been executed on this host`.

First Seen/Last Seen

The first/most recent date and time that events triggering the IOC occurred.

Domain

The domain of the host that triggered the IOC. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Related Topics

Event Searches, on page 2323

Editing Indication of Compromise Rule States for a Single Host or User

When enabled in a network discovery policy, indication of compromise rules apply to all hosts in the monitored network and to authoritative users that are associated with IOC events on that network. You can disable a rule for an individual host or user to avoid unhelpful IOC tags (for example, you may not want to see IOC tags for a DNS server.) If a rule is disabled in the applicable network discovery policy, it cannot be enabled for a specific host or user. Disabling a rule for a particular host does not affect tagging for the user involved in the same event, and vice-versa.

Step 1 Navigate to the **Indications of Compromise** section of a host or user profile.

Step 2 Click **Edit Rule States**.

Step 3 In the **Enabled** column for a rule, click the slider to enable or disable it.

Step 4 Click **Save**.

Viewing Source Events for Indication of Compromise Tags

You can use the Indications of Compromise section of the host profile and the user profile to navigate quickly to the events that triggered the IOC tags. Analyzing these events can give you the information you need to determine what, and whether, action is required to address threats of compromise.

Clicking **View** ( ) next to the timestamp of an IOC tag navigates to the table view of events for the relevant event type, constrained to show only the event that triggered the IOC tag.

Only the first instance of a User IOC is displayed in the Firepower Management Center. Subsequent instances are caught by the DNS Server."

Step 1 In a host or user profile, navigate to the **Indications of Compromise** section.

Step 2 Click **View** ( ) in the **First Seen** or **Last Seen** column for the IOC tag you want to investigate.

Resolving Indication of Compromise Tags

After you have analyzed and addressed the threats indicated by an indication of compromise (IOC) tag, or if you determine that an IOC tag represents a false positive, you can mark an event resolved. Marking an event resolved removes it from the host profile and the user profile; when all active IOC tags on a profile are resolved, the **Compromised Host** or a user is associated with an indication of compromise **Red User icon** no longer appears. You can still view the IOC-triggering events for the resolved IOC.

If the events that triggered the IOC tag recur, the tag is set again unless you have disabled the IOC rule for the host or user.

Step 1 In a host or user profile, navigate to the **Indications of Compromise** section.

Step 2 You have two choices:

- To mark an individual IOC tag resolved, click **Delete** ( ) to the right of the tag you want to resolve.

- To mark all IOC tags on the profile resolved, click **Mark All Resolved**.

Server Data

The Firepower System collects information about all servers running on hosts on monitored network segments. This information includes:

- the name of the server
- the application and network protocols used by the server
- the vendor and version of the server
- the IP address associated with the host running a server
- the port on which the server communicates

When the system detects a server, it generates a discovery event unless the associated host has already reached its maximum number of servers. You can use the Firepower Management Center web interface to view, search, and delete server events.

You can also base correlation rules on server events. For example, you could trigger a correlation rule when the system detects a chat server, such as ircd, running on one of your hosts.

The system can add hosts to the network map from exported NetFlow records, but the available information for these hosts is limited; see Differences between NetFlow and Managed Device Data, on page 1923.

Related Topics

Host Limits and Discovery Event Logging, on page 1979
Differences between NetFlow and Managed Device Data, on page 1923

Viewing Server Data

You can use the Firepower Management Center to view a table of detected servers. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access servers differs depending on the workflow you use. All the predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the server data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Servers**.
- If you are using a custom workflow that does not include the table view of servers, click **(switch workflow)**, then choose **Servers**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.

- Learn more about the contents of the columns in the table; see Server Data Fields, on page 2534.
- Edit server identities by checking the check boxes next to the events for servers you want to edit, then clicking **Set Server Identity**.
- Right-click an item in the table to see options. (Not every column offers options.)

Related Topics

Editing Server Identities, on page 2492

Server Data Fields

Descriptions of the fields that can be viewed and searched in the servers table follow below.

Last Used

The date and time the server was last used on the network or the date and time that the server was originally updated using the host input feature. The Last Used value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system detects a server information update.

IP Address

The IP address associated with the host running the server.

Port

The port where the server is running.

Protocol

The network or transport protocol used by the server.

Application Protocol

One of the following:

- the name of the application protocol for the server
- `pending` if the system cannot positively or negatively identify the server for one of several reasons
- `unknown` if the system cannot identify the server based on known server fingerprints or if the server was added through host input and did not include the application protocol

Category, Tags, Risk, or Business Relevance for Application Protocols

The categories, tags, risk level, and business relevance assigned to the application protocol. These filters can be used to focus on a specific set of data.

Vendor

One of the following:

- the server vendor as identified by the system, Nmap or another active source, or that you specified using the host input feature

- blank, if the system cannot identify its vendor based on known server fingerprints, or if the server was added to the network map using NetFlow data

Version

One of the following:

- the server version as identified by the system, Nmap or another active source, or that you specified using the host input feature
- blank, if the system cannot identify its version based on known server fingerprints, or if the server was added to the network map using NetFlow data

Web Application

The web application based on the payload content detected by the system in the HTTP traffic. Note that if the system detects an application protocol of `HTTP` but cannot detect a specific web application, the system supplies a generic web browsing designation.

Category, Tags, Risk, or Business Relevance for Web Applications

The categories, tags, risk level, and business relevance assigned to the web application. These filters can be used to focus on a specific set of data.

Hits

The number of times the server was accessed. For servers added using the host input feature, this value is always 0.

Source Type

One of the following values:

- User: user_name
- Application: app_name
- Scanner: scanner_type (Nmap or scanner added through network discovery configuration)
- `Firepower`, `Firepower Port Match`, or `Firepower Pattern Match` for servers detected by the Firepower System
- `NetFlow` for servers added using NetFlow data

Domain

The domain of the host running the server. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Device

Either the managed device that detected the traffic or the device that processed NetFlow or host input data.

Current User

The user identity (username) of the currently logged in user on the host.

When a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Count

The number of events that match the information that appears in each row. This field appears only after you apply a constraint that creates two or more identical rows.

Related Topics

Event Searches, on page 2323
Network Discovery Data Storage Settings, on page 2085

Application and Application Details Data

When a monitored host connects to another host, the system can, in many cases, determine what application was used. The Firepower System detects the use of many email, instant messaging, peer-to-peer, web applications, as well as other types of applications.

For each detected application, the system logs the IP address that used the application, the product, the version, and the number of times its use was detected. You can use the web interface to view, search, and delete application events. You can also update application data on a host or hosts using the host input feature.

If you know which applications are running on which hosts, you can use that knowledge to create host profile qualifications, which constrain the data you collect while building a traffic profile, and also can limit the conditions under which you want to trigger a correlation rule. You can also base correlation rules on the detection of application. For example, if you want your employees to use a specific mail client, you could trigger a correlation rule when the system detects a different mail client running on one of your hosts.

You can obtain the latest information about Firepower's application detectors by carefully reading both the release notes for each Firepower System update and advisories for each VDB update.

To collect and store application data for analysis, make sure that you enable application detection in your network discovery policy.

Viewing Application Data

You can use the Firepower Management Center to view a table of detected applications. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access applications differs depending on the workflow you use. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the application data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Application Details**.

- If you are using a custom workflow that does not include the table view of application details, click **(switch workflow)**, then choose **Clients**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Application Data Fields, on page 2537.
- Open the Application Detail View for a specific application by clicking **Application Detail View** next to a client, application protocol, or web application.
- View data in sources external to your Firepower system, by right-clicking an event value. The options you see depend on the data type and include public sources; other sources depend on the resources you have configured. For information, see Event Investigation Using Web-Based Resources, on page 2258
- Gather intelligence about an event by right-clicking an event value in the table and choosing from a Cisco or third-party intelligence source. For example, you can get details about a suspicious IP address from Cisco Talos. The options you see depend on the data type and the integrations that are configured on your system. For more information, see Event Investigation Using Web-Based Resources, on page 2258.

Application Data Fields

When the system detects traffic for a known client, application protocol, or web application, it logs information about the application and the host running it.

Descriptions of the fields that can be viewed and searched in the applications table follow.

Application

The name of the detected application.

IP Address

The IP address associated with the host using the application.

Type

The type of application:

Application Protocols

Represents communications between hosts.

Client Applications

Represents software running on a host.

Web Applications

Represents the content or requested URL for HTTP traffic.

Category

A general classification for the application that describes its most essential function. Each application belongs to at least one category.

Tag

Additional information about the application. Applications can have any number of tags, including none.

Risk

How likely the application is to be used for purposes that might be against your organization's security policy. An application's risk can range from Very Low to Very High.

Of Application Protocol Risk, Client Risk, and Web Application Risk, the highest of the three detected, when available, in the traffic that triggered the intrusion event.

Business Relevance

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally. An application's business relevance can range from Very Low to Very High.

Of Application Protocol Business Relevance, Client Business Relevance, and Web Application Business Relevance, the lowest of the three detected, when available, in the traffic that triggered the intrusion event.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Domain

The domain of the host using the application. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Related Topics

Event Searches, on page 2323

Viewing Application Detail Data

You can use the Firepower Management Center to view a table of detected application details. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access application details differs depending on the workflow you use. There are two predefined workflows. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the application details data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Application Details**.
- If you are using a custom workflow that does not include the table view of application details, click **(switch workflow)**, then select **Clients**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Application Detail Data Fields, on page 2539.
- Open the Application Detail View for a specific application by clicking **Application Detail View** next to a client.
- View data in available sources external to your Firepower system, by right-clicking an event value. The options you see depend on the data type and include public sources; other sources depend on the resources you have configured. For information, see Event Investigation Using Web-Based Resources, on page 2258
- Gather intelligence about an event by right-clicking an event value in the table and choosing from a Cisco or third-party intelligence source. For example, you can get details about a suspicious IP address from Cisco Talos. The options you see depend on the data type and the integrations that are configured on your system. For more information, see Event Investigation Using Web-Based Resources, on page 2258.

Application Detail Data Fields

When the system detects traffic for a known client, application protocol, or web application, it logs information about the application and the host running it.

Descriptions of the fields that can be viewed and searched in the application details table follow.

Last Used

The time that the application was last used or the time that the application data was updated using the host input feature. The Last Used value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system detects an application information update.

IP Address

The IP address associated with the host using the application.

Client

The name of the application. Note that if the system detected an application protocol but could not detect a specific client, `client` is appended to the application protocol name to provide a generic name.

Version

The version of the application.

Category, Tags, Risk, or Business Relevance for Clients, Application Protocols, and Web Applications

The categories, tags, risk level, and business relevance assigned to the application. These filters can be used to focus on a specific set of data.

Application Protocol

The application protocol used by the application. Note that if the system detected an application protocol but could not detect a specific client, `client` is appended to the application protocol name to provide a generic name.

Web Application

The web application based on the payload content or URL detected by the system in the HTTP traffic. Note that if the system detects an application protocol of HTTP but cannot detect a specific web application, the system supplies a generic web browsing designation here.

Hits

The number of times the system detected the application in use. For applications added using the host input feature, this value is always `0`.

Domain

The domain of the host using the application. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Device

The device that generated the discovery event containing the application detail.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Vulnerability Data

The Firepower System includes its own vulnerability tracking database which is used, in conjunction with the system's fingerprinting capability, to identify the vulnerabilities associated with the hosts on your network. The operating systems, servers, and clients running on your hosts have different sets of associated vulnerabilities.

You can use the Firepower Management Center to:

- Track and review the vulnerabilities for each host.

- Deactivate vulnerabilities for a host after you patch the host or otherwise judge it immune to a vulnerability.

Vulnerabilities for vendorless and versionless servers are not mapped unless the applications protocols used by the servers are mapped in the Firepower Management Center configuration. Vulnerabilities for vendorless and versionless clients cannot be mapped.

Related Topics

Mapping Vulnerabilities for Servers, on page 1056

Vulnerability Data Fields

Except as noted, these fields appear on all pages under **Analysis > Hosts > Vulnerabilities**.

Additional Information

This section is on the Vulnerability Details page. It is no longer in use.

Available Exploits

This information is no longer available and the field is blank.

Bugtraq ID

The third-party Bugtraq database is no longer available, so this field is blank.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

CVE ID

The identification number associated with the vulnerability in MITRE's Common Vulnerabilities and Exposures (CVE) database (https://cve.mitre.org/).

This field is available on the Vulnerability Details page. The CVE ID also appears at the beginning of the Title column in vulnerabilities tables.

Date Published

The date the vulnerability was published.

Description

A brief description of the vulnerability, from the National Vulnerability Database (NVD).

For the complete description, look up the CVE ID in the NVD.

Impact Qualification

This field is available only on the Vulnerability Details page.

Use the drop-down list to enable or disable a vulnerability. The Firepower Management Center ignores disabled vulnerabilities in its impact correlations.

The setting you specify here determines how the vulnerability is treated on a system-wide basis and is not limited to the host profile where you select the value.

Remote

Indicates whether the vulnerability is remotely exploitable (`TRUE`/`FALSE`).

Snort ID

The identification number associated with the vulnerability in the Snort ID (SID) database. That is, if an intrusion rule can detect network traffic that exploits a particular vulnerability, that vulnerability is associated with the intrusion rule's SID.

Note that a vulnerability can be associated with more than one SID (or no SIDs at all). If a vulnerability is associated with more than one SID, the vulnerabilities table includes a row for each SID.

Solution

This information is no longer available and the field is blank.

SVID

The vulnerability identification number that the Firepower system uses to track vulnerabilities.

To view details for this vulnerability, click **View** ( ).

Technical Description

The base score and Common Vulnerability Scoring System score (CVSS) from the National Vulnerability Database (NVD).

Title

The CVE ID of the vulnerability followed by its description.

Vulnerability Impact

The severity of the vulnerability on a scale of 0 to 10, with 10 being the most severe.

Event Searches, on page 2323

Vulnerability Deactivation

Deactivating a vulnerability prevents the system from using that vulnerability to evaluate intrusion impact correlations. You can deactivate a vulnerability after you patch the hosts on your network or otherwise judge them immune. Note that if the system discovers a new host that is affected by that vulnerability, the vulnerability is considered valid (and is not automatically deactivated) for that host.

Deactivating a vulnerability within a vulnerabilities workflow that is **not** constrained by IP addresses deactivates the vulnerability for *all* detected hosts on your network. You can deactivate vulnerabilities within the vulnerabilities workflow only on:

- the second page of the default vulnerabilities workflow, **Vulnerabilities on the Network**, which shows only the vulnerabilities that apply to the hosts on your network

- a page in a vulnerabilities workflow, custom or predefined, that you constrained based on IP address using a search.

You can deactivate a vulnerability for a single host using the network map, using the host's host profile, or by constraining the vulnerabilities workflow based on the IP addresses of the host or hosts for which you want to deactivate vulnerabilities. For hosts with multiple associated IP addresses, this function applies only to the single, selected IP address of that host.

In a multidomain deployment, deactivating a vulnerability in an ancestor domain deactivates it in all descendant domains. Leaf domains can activate or deactivate a vulnerability for their devices if the vulnerability is activated in the ancestor domain.

Viewing Vulnerability Data

You can use the Firepower Management Center to view a table of vulnerabilities. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access vulnerabilities differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of vulnerabilities. The table view contains a row for each vulnerability in the database, regardless of whether any of your detected hosts exhibit the vulnerabilities. The second page of the predefined workflow contains a row for each vulnerability (that you have not deactivated) that applies to detected hosts on your network. The predefined workflow terminates in a vulnerability detail view, which contains a detailed description for every vulnerability that meets your constraints.

Tip If you want to see the vulnerabilities that apply to a single host or set of hosts, perform a search for vulnerabilities, specifying an IP address or range of IP addresses for the hosts.

You can also create a custom workflow that displays only the information that matches your specific needs.

The table of vulnerabilities is not restricted by domain in a multidomain deployment.

Step 1 Access the table of vulnerabilities:

- If you are using the predefined vulnerabilities workflow, choose **Analysis** > **Hosts** > **Vulnerabilities**.
- If you are using a custom workflow that does not include the table view of vulnerabilities, click **(switch workflow)**, then choose **Vulnerabilities**.

Step 2 You have the following options:

- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Deactivate vulnerabilities so they are no longer used for intrusion impact correlation for currently vulnerable hosts; see Deactivating Multiple Vulnerabilities, on page 2544.
- View the details for a vulnerability by clicking **View** ( ) in the SVID column. Alternatively, constrain on the vulnerability ID and drill down to the vulnerability details page. See options for viewing additional details at Viewing Vulnerability Details, on page 2544.

- View the full text of a vulnerability title by right-clicking the title and choosing **Show Full Text**.

Viewing Vulnerability Details

You can view vulnerability details in any of the following ways:

- Choose **Analysis** > **Hosts** > **Vulnerabilities**, and click **View** ( ) next to the SVID.
- Choose **Analysis** > **Hosts** > **Third-Party Vulnerabilities** and click **View** ( ) next to the SVID.
- Choose **Analysis** > **Hosts** > **Network Map**, and click **Vulnerabilities**.
- View the profile of a host affected by the vulnerability (**Analysis** > **Hosts** > **Network Map**, click **Hosts**, then drill down and click the host you are investigating), and expand the **Vulnerabilities** section of the profile.

Deactivating Multiple Vulnerabilities

Deactivating a vulnerability within a vulnerabilities workflow that is **not** constrained by IP addresses deactivates the vulnerability for *all* detected hosts on your network.

In a multidomain deployment, deactivating a vulnerability in an ancestor domain deactivates it in all descendant domains. Leaf domains can activate or deactivate a vulnerability for their devices so long as the vulnerability is activated in the ancestor domain.

Step 1 Access the table of vulnerabilities:

- If you are using the predefined vulnerabilities workflow, choose **Analysis** > **Hosts** > **Vulnerabilities**.
- If you are using a custom workflow that does not include the table view of vulnerabilities, click **(switch workflow)**, then choose **Vulnerabilities**.

Step 2 Click **Vulnerabilities on the Network**.

Step 3 Check the check boxes next to vulnerabilities you want to deactivate.

Step 4 Click **Review** at the bottom of the page.

Third-Party Vulnerability Data

The Firepower System includes its own vulnerability tracking database which is used, in conjunction with the system's fingerprinting capability, to identify the vulnerabilities associated with the hosts on your network.

You can augment the system's vulnerability data with imported network map data from third-party applications. To do so, your organization must be able to write scripts or create command line import files to import the data. For more information, see the *Firepower System Host Input API Guide*.

To include imported data in impact correlations, you must map third-party vulnerability information to the operating system and application definitions in the database. You cannot map third-party vulnerability information to client definitions.

Viewing Third-Party Vulnerability Data

After you use the host input feature to import third-party vulnerability data, you can use the Firepower Management Center to view a table of third-party vulnerabilities. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access third-party vulnerabilities differs depending on the workflow you use. There are two predefined workflows. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the third-party vulnerabilities data:

- If you are using the predefined workflow, choose **Analysis** > **Hosts** > **Third-Party Vulnerabilities**.
- If you are using a custom workflow that does not include the table view of third-party vulnerabilities, click **(switch workflow)**, then choose **Vulnerabilities by Source** or **Vulnerabilities by IP Address**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Third-Party Vulnerability Data Fields, on page 2545.
- View the vulnerability details for a third-party vulnerability by clicking **View** ( ) in the SVID column. Alternatively, constrain on the vulnerability ID and drill down to the vulnerability details page.

Third-Party Vulnerability Data Fields

Descriptions of the fields that can be viewed and searched in the third-party vulnerabilities table follow.

Vulnerability Source

The source of the third-party vulnerabilities, for example, QualysGuard or NeXpose.

Vulnerability ID

The ID number associated with the vulnerability for its source.

IP Address

The IP address associated with the host affected by the vulnerability.

Port

A port number, if the vulnerability is associated with a server running on a specific port.

Bugtraq ID

The identification number associated with the vulnerability in the Bugtraq database. (http://www.securityfocus.com/bid/)

CVE ID

The identification number associated with the vulnerability in MITRE's Common Vulnerabilities and Exposures (CVE) database (https://cve.mitre.org/).

SVID

The legacy vulnerability identification number that the system uses to track vulnerabilities

Click **View** () to access the vulnerability details for the SVID.

Snort ID

The identification number associated with the vulnerability in the Snort ID (SID) database. That is, if an intrusion rule can detect network traffic that exploits a particular vulnerability, that vulnerability is associated with the intrusion rule's SID.

Note that a vulnerability can be associated with more than one SID (or no SIDs at all). If a vulnerability is associated with more than one SID, the vulnerabilities table includes a row for each SID.

Title

The title of the vulnerability.

Description

A brief description of the vulnerability.

Domain

The domain of the host with the vulnerability. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Active Sessions, Users, and User Activity Data

Identity sources collect active session data, user data, and user activity data. The data is displayed in individual user-related workflows:

- Active Sessions — this workflow displays all current user sessions on your network. A single user running several simultaneous active sessions would occupy several rows in this table. For more information about the types of user data displayed in this workflow, see Active Sessions Data, on page 2553.

- Users — this workflow displays all users seen on your network. A single user occupies a single row in this table. For more information about the types of user data displayed in this workflow, see User Data, on page 2554.
- User Activity — this workflow displays all user activity seen on your network. A single user with more than one instance of user activity would occupy several rows in this table. For more information about the types of user activity displayed in this workflow, see User Activity Data, on page 2557.

For more information about the identity sources that populate these workflows, see About User Identity Sources, on page 1926.

User-Related Fields

User-related data is displayed in the active sessions, users, and user activity tables.

Table 331: Active Sessions, Users, and User Activity Field Descriptions

Field	Description	Active Sessions Table	Users Table	User Activity Table
Active Session Count	The number of active sessions associated with the user.	No	Yes	No
Authentication Type	The type of authentication: `No Authentication`, `Passive Authentication`, `Active Authentication`, `Guest Authentication`, `Failed Authentication`, or `VPN Authentication`. For more information about the supported identity sources for each Authentication Type, seeAbout User Identity Sources, on page 1926.	Yes	No	Yes
Available for Policy	A value of **Yes** means the user was retrieved from the user store (for example, Active Directory). A value of **No** means the FMC received a report of a login for that user but the user is not in the user store. One way this can happen is if a user in an excluded group logs in to the user store. You can exclude groups from being downloaded when you configure a realm. Users not available for policy are recorded in the FMC but are not sent to managed devices.	No	Yes	No
Count	**Note** The **Count** field is displayed only after you apply a constraint that creates two or more identical rows. Depending on the table, the number of sessions, users, or activity events that match the information that appears in a particular row.	Yes	Yes	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
Current IP	The IP address associated with the host that the user is logged into. This field is blank in the Users table if there are no active sessions for a user.	Yes	Yes	No
Department	The user's department, as obtained by a realm. If there is no department explicitly associated with the user on your servers, the department is listed as whatever default group the server assigns. For example, on Active Directory, this is `Users (ad)`. This field is blank if: • You have not configured a realm. • The Firepower Management Center cannot correlate the user in the FMC database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login).	Yes	Yes	No
Description	More information, if available, about the session, user, or user activity.	No	No	Yes
Device	For user activity detected by traffic-based detection or an active authentication identity source, the name of the device that identified the user. For other types of user activity, the managing Firepower Management Center. **Note** If you have configured your VPN in a high-availability deployment, the device name displayed against active VPN sessions can be the primary or secondary device that identified the user session.	Yes	No	Yes
Discovery Application	The application or protocol used to detect the user. • For user activity detected by traffic-based detection, one of the following: ldap, pop3, imap, oracle, sip, http, ftp, mdns, or aim. **Note** Users are not added to the database based on SMTP logins. • For all other user activity: ldap.	Yes	Yes	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
Current IP Domain/Domain	In the Active Sessions table, the multitenancy domain where the user activity was detected. In the Users table, the multitenancy domain associated with the user's realm. In the User Activity table, the multitenancy domain where the user activity was detected. This field is only present if you have ever configured the Firepower Management Center for multitenancy.	Yes	Yes	Yes
E-Mail	The user's email address. This field is blank if: • The user was added to the database via an AIM login. • The user was added to the database via an LDAP login and there is no email address associated with the user on your LDAP servers.	Yes	Yes	No
End Port	If the user was reported by the TS Agent and their session is currently active, this field identifies the end value for the port range assigned to the user. This field is blank if the user's TS Agent session is inactive or if the user was reported by another identity source.	Yes	No	Yes
Endpoint Location	The IP address of the network device that used ISE to authenticate the user, as identified by ISE. If you do not configure ISE, this field is blank.	No	No	Yes
Endpoint Profile	The user's endpoint device type, as identified by Cisco ISE. If you do not configure ISE, this field is blank.	No	No	Yes
Event	The user activity event type.	No	No	Yes
First Name	The user's first name, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Firepower Management Center cannot correlate the user in the FMC database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no first name associated with the user on your servers.	Yes	Yes	No

Field	Description	Active Sessions Table	Users Table	User Activity Table
IP Address	For **User Login** user activity, the IP address or internal IP address involved in the login: • LDAP, POP3, IMAP, FTP, HTTP, MDNS, and AIM logins — the address of the user's host • SMTP and Oracle logins — the address of the server • SIP logins — the address of the session originator An associated IP address does not mean the user is the current user for that IP address; when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. For other types of user activity, this field is blank.	No	No	Yes
Last Name	The user's last name, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Firepower Management Center cannot correlate the user in the FMC database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no last name associated with the user on your servers.	Yes	Yes	No
Last Seen	The date and time that a session was last initiated (or user data was updated) for the user.	Yes	Yes	No
Login Time	The date and time that the session was initiated for the user.	Yes	No	No
Phone	The user's telephone number, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Firepower Management Center cannot correlate the user in the FMC database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no telephone number associated with the user on your servers.	Yes	Yes	No

Field	Description	Active Sessions Table	Users Table	User Activity Table
Realm	The identity realm associated with the user.	Yes	Yes	Yes
Security Group Tag	The Security Group Tag (SGT) attribute applied by Cisco TrustSec as the packet entered a trusted TrustSec network. If you do not configure ISE, this field is blank.	No	No	Yes
Session Duration	The duration of the user session, calculated from the **Login Time** and the current time.	Yes	No	No
Start Port	If the user was reported by the TS Agent and their session is currently active, this field identifies the start value for the port range assigned to the user. This field is blank if the user's TS Agent session is inactive or if the user was reported by another identity source.	Yes	No	Yes
Time	The time that the system detected the user activity.	No	No	Yes
User	At minimum, this field displays the user's realm and username. For example, `Lobby\jsmith`, where Lobby is the realm and jsmith is the username. If a realm downloads additional user data from an LDAP server and the system associates it with a user, this field also displays the user's first name, last name, and type. For example, `John Smith (Lobby\jsmith, LDAP)`, where John Smith is the user's name and LDAP is the type. **Note** Because traffic-based detection can record unsuccessful AIM logins, the Firepower Management Center may store invalid AIM users (for example, if a user misspelled his or her username).	Yes	Yes	No
Username	The username associated with the user.	Yes	Yes	Yes
VPN Bytes In	For Remote Access VPN-reported user activity, the total number of bytes received from the remote peer or client by the Firepower Threat Defense. **Note** You can view the total number of bytes received once the user's VPN session is terminated. For ongoing VPN sessions, this is not a dynamic counter. For other types of user activity, this field is blank.	No	No	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
VPN Bytes Out	For Remote Access VPN-reported user activity, the total number of bytes transmitted to the remote peer or client by the Firepower Threat Defense. **Note** You can view the total number of bytes transmitted once the user's VPN session is terminated. For ongoing VPN sessions, this is not a dynamic counter. For other types of user activity, this field is blank.	No	No	Yes
VPN Client Application	For Remote Access VPN-reported user activity, the remote user's AnyConnect VPN client application. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Client Country	For Remote Access VPN-reported user activity, the country name as reported by the AnyConnect VPN client. For other types of user activity, this field is blank.	No	No	Yes
VPN Client OS	For Remote Access VPN-reported user activity, the remote user's endpoint operating system as reported by the AnyConnect VPN client. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Client Public IP	For Remote Access VPN-reported user activity, the publicly routable IP address of the AnyConnect VPN client device. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Connection Duration	For Remote Access VPN-reported user activity, the total time (HH:MM:SS) that the session was active. For other types of user activity, this field is blank.	No	No	Yes
VPN Connection Profile	For Remote Access VPN-reported user activity, the name of the connection profile (tunnel group) used by the VPN session. Connection profiles are part of a Remote Access VPN Policy. For other types of user activity, this field is blank.	Yes	No	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
VPN Group Policy	For Remote Access VPN-reported user activity, the name of the group policy assigned to the client when the VPN session is established; either the statically-assigned group policy associated with the VPN Connection Profile, or the dynamically-assigned group policy if RADIUS is used for authentication. If assigned by the RADIUS server, this group policy overrides the static policy configured for the VPN Connection Profile. Group policies configure common attributes for groups of users in Remote Access VPN policies. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Session Type	For Remote Access VPN-reported user activity, the type of session: LAN-to-LAN or Remote. For other types of user activity, this field is blank.	Yes	No	Yes

Active Sessions Data

The **Analysis** > **Users** > **Active Sessions** workflow displays select information about current user sessions. When a user on your network runs several sessions simultaneously, the Firepower System can uniquely identify the sessions if:

- they have unique **IP Address** values.
- they have unique **Start Port** and **End Port** values, as provided by the Cisco Terminal Services (TS) Agent.
- they have unique **Current IP Domain** values.
- they were authenticated by different identity sources.
- they were associated with different identity realms.

For more information about the user and user activity data stored by the system, see User Data, on page 2554 and User Activity Data, on page 2557.

For information about general user-related event troubleshooting, see Troubleshoot Realms and User Downloads, on page 2009. For information about Remote Access VPN Troubleshooting, see VPN Troubleshooting for Firepower Threat Defense, on page 935.

Viewing Active Session Data

You can view a table of active sessions, and then manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access users differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of users that lists all detected users, and terminates in a user details page. The user details page provides information on every user that meets your constraints.

Step 1 Access the users data:

- If you are using the predefined workflow, choose **Analysis** > **Users** > **Active Sessions**.
- If you are using a custom workflow that does not include the table view of active sessions, click **(switch workflow)**, then choose **Active Sessions**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see Active Sessions Data, on page 2553 and User-Related Fields, on page 2547.

User Data

When an identity source reports a user login for a user who is not already in the database, the user is added to the database, unless you have specifically restricted that login type.

The system updates the users database when one of the following occurs:

- A user on the Firepower Management Center manually deletes a non-authoritative user from the Users table.
- An identity source reports a logoff by that user.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Note If you have ISE/ISE-PIC configured, you may see host data in the users table. Because host detection by ISE/ISE-PIC is not fully supported, you cannot perform user control using ISE-reported host data.

The type of user login that the system detected determines what information is stored about the new user.

Identity Source	Login Type	User Data Stored
ISE/ISE-PIC	Active Directory LDAP RADIUS RSA	• username • current IP address • Security Group Tag (SGT) — not supported with ISE-PIC • endpoint profile/device type — not supported with ISE-PIC • endpoint location/location IP — not supported with ISE-PIC • type (LDAP)

Identity Source	Login Type	User Data Stored
User Agent	Active Directory	• username • current IP address • type (LDAP)
TS Agent	Active Directory	• username • current IP address • start port • end port • type (LDAP)
captive portal	Active Directory LDAP	• username • current IP address • type (LDAP)
traffic-based detection	LDAP AIM Oracle SIP HTTP FTP MDNS	• username • current IP address • type (AD)
	POP3 IMAP	• username • current IP address • email address • type (`pop3` or `imap`)

If you configure a realm to automatically download users, the Firepower Management Center queries the servers based on the interval you specified. It may take five to ten minutes for the Firepower Management Center database to update with user metadata after the system detects a new user login. The Firepower Management Center obtains the following information and metadata about each user:

- username
- first and last names
- email address
- department

- telephone number
- current IP address
- Security Group Tag (SGT), if available
- endpoint profile, if available
- endpoint location, if available
- start port, if available
- end port, if available

The number of users the Firepower Management Center can store in its database depends on your Firepower Management Center model. When a non-authoritative user login to a host is detected, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user login is detected for that host, only another authoritative user login changes the current user.

Note that traffic-based detection of AIM, Oracle, and SIP logins create duplicate user records because they are not associated with any of the user metadata that the system obtains from LDAP servers. To prevent overuse of user count because of duplicate user records from these protocols, configure traffic-based detection to ignore those protocols.

You can search, view, and delete users from the database; you can also purge all users from the database.

For information about general user-related event troubleshooting, see Troubleshoot Realms and User Downloads, on page 2009.

Viewing User Data

You can view a table of users, and then manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access users differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of users that lists all detected users, and terminates in a user details page. The user details page provides information on every user that meets your constraints.

Step 1 Access the users data:

- If you are using the predefined workflow, choose **Analysis** > **Users** > **Users**.
- If you are using a custom workflow that does not include the table view of users, click **(switch workflow)**, then choose **Users**.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see User-Related Fields, on page 2547.

User Activity Data

The Firepower System generates events that communicate the details of user activity on your network. When the system detects user activity, the user activity data is logged to the database. You can view, search, and delete user activity; you can also purge all user activity from the database.

The system logs a user activity event when a user is seen on your network for the first time. Subsequent appearances by that user do not log new user activity events. However, if the user's IP address changes, the system logs a new user activity event.

The Firepower System also correlates user activity with other types of events. For example, intrusion events can tell you the users who were logged into the source and destination hosts at the time of the event. This correlation can tell you who was logged into the host that was targeted by an attack, or who initiated an internal attack or portscan.

You can also use user activity in correlation rules. Based on the type of user activity as well as other criteria that you specify, you can build correlation rules that, when used in a correlation policy, launch remediations and alert responses when network traffic meets your criteria.

Note If you have ISE/ISE-PIC configured, you may see host data in the users table. Because host detection by ISE/ISE-PIC is not fully supported, you cannot perform user control using ISE-reported host data.

Descriptions of the four types of user activity data follow.

New User Identity

This type of event is generated when the system detects a login by an unknown user that is not in the database.

The system logs a user activity event when a user is seen on your network for the first time. Subsequent appearances by that user do not log new user activity events. However, if the user's IP address changes, the system logs a new user activity event.

User Login

This type of event is generated when any of the following occur:

- Captive portal performs a successful or failed user authentication.
- Traffic-based detection detects a successful or failed user login.

Note SMTP logins detected by traffic-based detection are not recorded unless there is already a user with a matching email address in the database.

When a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user.

If you are using captive portal or traffic-based detection, note the following about failed user login and failed user authentication data:

- Failed logins reported by traffic-based detection (LDAP, IMAP, FTP, and POP3 traffic) are displayed in the table view of user activity, but not in the table view of users. If a known user failed to log in, the system identifies them by their username. If an unknown user failed to log in, the system uses **Failed Authentication** as their username.
- Failed authentications reported by captive portal are displayed in both the table view of user activity and the table view of users. If a known user failed to authenticate, the system identifies them by their username. If an unknown user failed to authenticate, the system identifies them by the username they entered.

Delete User Identity

This type of event is generated when you manually delete a user from the database.

User Identity Dropped: User Limit Reached

This type of event is generated when the system detects a user that is not in the database, but cannot add the user because you have reached the maximum number of users in the database as determined by your Firepower Management Center model.

After you reach the user limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database.

However, the system favors authoritative users. If you have reached the limit and the system detects a login for a previously undetected authoritative user, the system deletes the non-authoritative user who has remained inactive for the longest time, and replaces it with the new authoritative user.

User Indications of Compromise Events

The following user IOC changes are logged in the user activity database:

- When indications of compromise are resolved.
- When indication of compromise rules are enabled or disabled for users.

For information about general user-related event troubleshooting, see Troubleshoot Realms and User Downloads, on page 2009.

Related Topics

The User Activity Database, on page 1932

Viewing User Activity Data

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

You can view a table of user activity, and then manipulate the event view depending on the information you are looking for. The page you see when you access user activity differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of user activity and terminates in a user details page, which contains user details for every user that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs.

Step 1 Access the user activity data:

- If you are using the predefined workflow, choose **Analysis** > **Users** > **User Activity**.

- If you are using a custom workflow that does not include the table view of user activity, click **(switch workflow)**, then choose **User Activity**.

Tip If no events appear, you may need to adjust the time range; see Changing the Time Window, on page 2314.

Step 2 You have the following options:

- Use a different workflow, including a custom workflow, by clicking **(switch workflow)**.
- Perform basic workflow actions; see Using Discovery and Identity Workflows, on page 2512.
- Learn more about the contents of the columns in the table; see User-Related Fields, on page 2547.

User Profile and Host History

You can learn more about a specific user by viewing the User pop-up window. The page that appears, called the "User Profile" in this document, is titled "User Identity" in the web interface.

You can display the window from:

- any event view that associates user data with other kinds of events
- the table view of active sessions
- the table view of users

User information also appears in the terminating page for users workflows.

The user data you see is the same as you would see in the table view of users.

Indications of Compromise Section

For information about this section, see:

- Indications of Compromise, on page 2084
- Indications of Compromise Data Fields, on page 2531
- Editing Indication of Compromise Rule States for a Single Host or User, on page 2532
- Resolving Indication of Compromise Tags, on page 2532
- Viewing Source Events for Indication of Compromise Tags, on page 2532

Host History Section

The host history provides a graphic representation of the last twenty-four hours of the user's activity. A list of IP addresses of the hosts that the user logged into and logged off of approximates login and logout times with bar graphs. A typical user might log on to and off of multiple hosts in the course of a day. For example, periodic automated logins to a mail server would display as multiple short sessions, while longer logins (such as during working hours) display longer sessions.

If you use traffic-based detection or captive portal to capture failed logins, the host history also includes hosts where the user failed to log in.

The data used to generate the host history is stored in the user history database, which by default stores 10 million user login events. If you do not see any data in the host history for a particular user, either that user is inactive, or you may need to increase the database limit.

Related Topics

User Data Fields

Viewing User Details and Host History

You have two options:

- In any event view that lists users, click user that appears next to a user identity **User icon**, or, for users associated with an indication of compromise, **Red User icon**.
- In any users workflow, click the Users terminating page.

History for Working with Discovery Events

Table 332:

Feature	Version	Details
Vulnerability data changes	All	The Bugtraq resource for vulnerability data is no longer available. Where possible, vulnerability information is now updated from the National Vulnerability Database (NVD). However, Bugtraq ID, Solution, Available Exploits, and Additional Information will remain blank. Modified screens: • All pages under Analysis > Hosts > Vulnerabilities • Hosts and Vulnerabilities tabs on Analysis > Hosts > Network Map pages Supported Platforms: FMC

CHAPTER 125

Correlation and Compliance Events

The following topics describe how to view correlation and compliance events.

Viewing Correlation Events

When a correlation rule within an active correlation policy triggers, the system generates a correlation event and logs it to the database.

Note When a compliance white list within an active correlation policy triggers, the system generates a white list event.

You can view a table of correlation events, then manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access correlation events differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of correlation events. You can also create a custom workflow that displays only the information that matches your specific needs.

Before you begin

You must be an Admin or Security Analyst user to perform this task.

Step 1 Choose **Analysis** > **Correlation** > **Correlation Events** .

Optionally, to use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title.

Tip If you are using a custom workflow that does not include the table view of correlation events, click **(switch workflow)**, then choose **Correlation Events**.

Step 2 Optionally, adjust the time range as described in Changing the Time Window, on page 2314.

Step 3 Perform any of the following actions:

- To learn more about the columns that appear, see Correlation Event Fields, on page 2562.
- To view the host profile for an IP address, click host profile that appears next to the IP address.
- To view user identity information, click the user icon that appears next to the **User Identity**, or for users associated with IOCs,**Red User**.
- To sort and constrain events or to navigate within the current workflow page, see Using Workflows, on page 2294.
- To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- To drill down to the next page in the Workflows, constraining on a specific value, see Using Drill-Down Pages, on page 2301.
- To delete some or all correlation events, check the check boxes next to the events you want to delete and click **Delete**, or click **Delete All** and confirm you want to delete all the events in the current constrained view.
- To navigate to other event views to view associated events, see Inter-Workflow Navigation, on page 2319.
- To view data in available sources external to your Firepower system, right-click an event value. The options you see depend on the data type and include public sources; other sources depend on the resources you have configured. For information, see Event Investigation Using Web-Based Resources, on page 2258
- To gather intelligence about an event, right-click an event value in the table and choose from a Cisco or third-party intelligence source. For example, you can get details about a suspicious IP address from Cisco Talos. The options you see depend on the data type and the integrations that are configured on your system. For more information, see Event Investigation Using Web-Based Resources, on page 2258.

Database Event Limits, on page 1019
Workflow Pages, on page 2297

Correlation Event Fields

When a correlation rule triggers, the system generates a correlation event. The fields in the correlation events table that can be viewed and searched are described in the following table.

Table 333: Correlation Event Fields

Field	Description
Description	The description of the correlation event. The information in the description depends on how the rule was triggered. For example, if the rule was triggered by an operating system information update event, the new operating system name and confidence level appears.
Device	The name of the device that generated the event that triggered the policy violation.

Field	Description
Domain	The domain of the device whose monitored traffic triggered the policy violation. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Impact	The impact level assigned to the correlation event based on the correlation between intrusion data, discovery data, and vulnerability information. When searching this field, valid case-insensitive values are `Impact 0`, `Impact Level 0`, `Impact 1`, `Impact Level 1`, `Impact 2`, `Impact Level 2`, `Impact 3`, `Impact Level 3`, `Impact 4`, and `Impact Level 4`. Do not use impact icon colors or partial strings (for example, do not use `blue`, `level 1`, or `0`).
Ingress Interface or Egress Interface	The ingress or egress interface in the intrusion or connection event that triggered the policy violation.
Ingress Security Zone or Egress Security Zone	The ingress or egress security zone in the intrusion or connection event that triggered the policy violation.
Inline Result	One of: • a black down arrow, indicating that the system dropped the packet that triggered the intrusion rule • a gray down arrow, indicating that the system would have dropped the packet in an inline, switched, or routed deployment if you enabled the **Drop when Inline** intrusion policy option • blank, indicating that the triggered intrusion rule was not set to Drop and Generate Events When using this field to search for policy violations triggered by intrusion events, type either: • `dropped`, to specify whether the packet was dropped in an inline, switched, or routed deployment • `would have dropped`, to specify whether the packet would have dropped if the intrusion policy had been set to drop packets in an inline, switched, or routed deployment Note that the system does not drop packets in a passive deployment, including when an inline set is in tap mode, regardless of the rule state or the drop behavior of the intrusion policy.
Policy	The name of the policy that was violated.
Priority	The priority of the correlation event, which is determined by the priority of either the triggered rule or the violated correlation policy. When searching this field, enter `none` for no priority.

Field	Description
Rule	The name of the rule that triggered the policy violation.
Security Intelligence Category	The name of the object that represents or contains the blocked IP address in the event that triggered the policy violation. When searching this field, specify the Security Intelligence category associated with the correlation event that triggered the policy violation. The Security Intelligence category can be the name of a Security Intelligence object, the global Block list, a custom Security Intelligence list or feed, or one of the categories in the Intelligence Feed.
Source Continent or Destination Continent	The continent associated with the source or destination host IP addresses in the event that triggered the policy violation.
Source Country or Destination Country	The country associated with the source or destination IP address in the event that triggered the policy violation.
Source Host Criticality or Destination Host Criticality	The user-assigned host criticality of the source or destination host involved in the correlation event: `None`, `Low`, `Medium`, or `High`. Note that only correlation events generated by rules based on discovery events, host input events, or connection events contain a source host criticality.
Source IP or Destination IP	The IP address of the source or destination host in the event that triggered the policy violation.
Source Port/ICMP Type or Destination Port/ICMP Code	The source port or ICMP type for the source traffic or the destination port or ICMP code for destination traffic associated with the event that triggered the policy violation.
Source User or Destination User	The name of the user logged in to the source or destination host in the event that triggered the policy violation.
Time	The date and time that the correlation event was generated. This field is not searchable.
Count	The number of events that match the information that appears in each row. Note that the **Count** field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable

Using Compliance White List Workflows

The Firepower Management Center provides a set of workflows that you can use to analyze the white list events and violations that are generated for your network. The workflows are, along with the network map and dashboard, a key source of information about the compliance of your network assets.

The system provides predefined workflows for white list events and violations. You can also create custom workflows. When you are using a compliance white list workflow, you can perform many common actions.

Before you begin

You must be an Admin, Security Analyst, or Discovery Admin user to perform this task.

Step 1 Access a white list workflow using the **Analysis** > **Correlation** menu.

Step 2 You have the following options:

- Switch Workflow — To use a different workflow, including a custom workflow, click **(switch workflow)**.
- Time Range — To adjust the time range, which is useful if no events appear, see Changing the Time Window, on page 2314.
- Host Profile — To view the host profile for an IP address, click **Host Profile**() or, for hosts with active indications of compromise (IOC) tags, the **Compromised Host** that appears next to the IP address.
- User Profile (events only) — To view user identity information, click the user icon that appears next to the **User Identity**, or for users associated with IOCs,**Red User**.
- Constrain — To constrain the columns that appear, click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

  Tip To hide or show other columns, select or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, expand the search constraints, then click the column name under Disabled Columns.

- Drill Down — See Using Drill-Down Pages, on page 2301.
- Sort — To sort data in a workflow, click the column title. Click the column title again to reverse the sort order.
- Navigate This Page — See Workflow Page Traversal Tools, on page 2299.
- Navigate Between Pages — To navigate between pages in the current workflow, keeping the current constraints, click the appropriate page link at the top left of the workflow page.
- Navigate Between Event Views — To navigate to other event views to view associated events, click **Jump to** and select the event view from the drop-down list.
- Delete Events (events only) — To delete some or all items in the current constrained view, select the check boxes next to items you want to delete and click **Delete** or click **Delete All**.

Configuring Event View Settings, on page 33

Viewing White List Events

After its initial evaluation, the system generates a *white list event* whenever a monitored host goes out of compliance with an active white list. White list events are a special kind of correlation event, and are logged to the FMC correlation event database.

You can use the Firepower Management Center to view a table of compliance white list events. Then, you can manipulate the event view depending on the information you are looking for.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

The page you see when you access white list events differs depending on the workflow you use. You can use a predefined workflow, which terminates in a table view of events. You can also create a custom workflow that displays only the information that matches your specific needs.

Before you begin

You must be an Admin, Security Analyst, or Discovery Admin user to perform this task.

Step 1 Choose **Analysis** > **Correlation**> **White List Events**.

Step 2 You have the following options:

- To perform basic workflow actions, see Using Compliance White List Workflows, on page 2565.
- To learn more about the contents of the columns in the table, see White List Event Fields, on page 2566.
- To see more options, right-click values in the table.

White List Event Fields

White list events, which you can view and search using workflows, contain the following fields.

Device

The name of the managed device that detected the white list violation.

Description

A description of how the white list was violated. For example:

```
Client "AOL Instant Messenger" is not allowed.
```

Violations that involve an application protocol indicate the application protocol name and version, as well as the port and protocol (TCP or UDP) it is using. If you restrict prohibitions to a particular operating system, the description includes the operating system name. For example:

```
Server "ssh / 22 TCP (OpenSSH 3.6.1p2)" is not allowed on Operating System
"Linux Linux 2.4 or 2.6".
```

Domain

The domain of the host that has become non-compliant with the white list. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Host Criticality

The user-assigned host criticality of the source host that is out of compliance with the white list: None, Low, Medium, or High.

IP Address

The IP address of the host that has become non-compliant with the white list.

Policy

The name of the correlation policy that was violated, that is, the correlation policy that includes the white list.

Port

The port, if any, associated with the discovery event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.

Priority

The priority specified by the policy or white list that triggered the policy violation. This is determined either by the priority of the white list in a correlation policy or by the priority of the correlation policy itself. Note that the white list priority overrides the priority of its policy. When searching this field, enter `none` for no priority.

Time

The date and time that the white list event was generated. This field is not searchable.

User

The identity of any known user logged in to the host that has become non-compliant with the white list.

White List

The name of the white list.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

Viewing White List Violations

The system keeps a record of the current *white list violations* on your network. Each violation represents something disallowed running on one of your hosts. If a host becomes compliant, the system removes the now-corrected violation from the database.

You can use the Firepower Management Center to view a table of white list violations for all active white lists. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access white list violations differs depending on the workflow you use. The predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Step 1 Choose **Analysis** > **Correlation** > **White List Violations**.

Step 2 You have the following options:

- To perform basic workflow actions, see Using Compliance White List Workflows, on page 2565.
- To learn more about the contents of the columns in the table, see White List Violation Fields, on page 2568.
- To see more options, right-click values in the table.

White List Violation Fields

White list violations, which you can view and search using workflows, contain the following fields.

Domain

The domain where the non-compliant host resides. This field is only present if you have ever configured the Firepower Management Center for multitenancy.

Information

Any available vendor, product, or version information associated with the white list violation. For protocols that violate a white list, this field also indicates whether the violation is due to a network or transport protocol.

IP Address

The IP address of the non-compliant host.

Port

The port, if any, associated with the event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.

Protocol

The protocol, if any, associated with the event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.

Time

The date and time that the white list violation was detected.

Type

The type of white list violation, that is, whether the violation occurred as a result of a non-compliant:

- operating system (os) (When searching this field, enter **os** or **operating system**.)
- application protocol (server)
- client
- protocol
- web application (web) (When searching this field, enter **web application**.)

White List

The name of the white list that was violated.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

Remediation Status Events

When a remediation triggers, the system logs a remediation status event to the database. These events can be viewed on the Remediation Status page. You can search, view, and delete remediation status events.

Related Topics

Remediation Status Table Fields, on page 2570

Viewing Remediation Status Events

The page you see when you access remediation status events differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of remediations. The table view contains a row for each remediation status event. You can also create a custom workflow that displays only the information that matches your specific needs.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

You must be an Admin user to perform this task.

Step 1 Choose **Analysis** > **Correlation** > **Status**.

Step 2 Optionally, adjust the time range as described in Changing the Time Window, on page 2314.

Step 3 Optionally, to use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title.

Tip If you are using a custom workflow that does not include the table view of remediations, click **(switch workflow)** menu by the workflow title, then choose **Remediation Status**.

Step 4 You have the following options:

- To learn more about the columns that appear, see Remediation Status Table Fields, on page 2570.
- To sort and constrain the events, see Using Workflows, on page 2294.
- To navigate to the correlation events view to see associated events, click **Correlation Events**.
- To bookmark the current page so that you can quickly return to it, click **Bookmark This Page**. To navigate to the bookmark management page, click **View Bookmarks**.
- To generate a report based on the data in the table view, click **Report Designer** as described in Creating a Report Template from an Event View, on page 2174.
- To drill down to the next page in the workflow, see Using Drill-Down Pages, on page 2301.
- To delete remediation status events from the system, check the check boxes next to events you want to delete and click **Delete** or click **Delete All** and confirm you want to delete all the events in the current constrained view.
- To search for remediation status events, click **Search**.

Using Workflows, on page 2294

Remediation Status Table Fields

The following table describes the fields in the remediation status table that can be viewed and searched.

Table 334: Remediation Status Fields

Field	Description
Domain	The domain of the device whose monitored traffic triggered the policy violation, that in turn triggered the remediation. This field is only present if you have ever configured the Firepower Management Center for multitenancy.
Policy	The name of the correlation policy that was violated and triggered the remediation.
Remediation Name	The name of the remediation that was launched.

Field	Description
Result Message	A message that describes what happened when the remediation was launched. Status messages include: • Successful completion of remediation • Error in the input provided to the remediation module • Error in the remediation module configuration • Error logging into the remote device or server • Unable to gain required privileges on remote device or server • Timeout logging into remote device or server • Timeout executing remote commands or servers • The remote device or server was unreachable • The remediation was attempted but failed • Failed to execute remediation program • Unknown/unexpected error If custom remediation modules are installed, you may see additional status messages that are implemented by the custom module.
Rule	The name of the correlation rule that triggered the remediation.
Time	The date and time that the Firepower Management Center launched the remediation
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

Related Topics

Event Searches, on page 2323

Using the Remediation Status Events Table

You can change the layout of the event view or constrain the events in the view by a field value.

When you disable a column, it is disabled for the duration of your session unless you add it back later. If you disable the first column, the Count column is added.

Clicking a value within a row in a table view constrains the table view and does not drill down to the next page.

Tip Table views always include “Table View” in the page name.

In a multidomain deployment, you can view data for the current domain and for any descendant domains. You cannot view data from higher level or sibling domains.

Before you begin

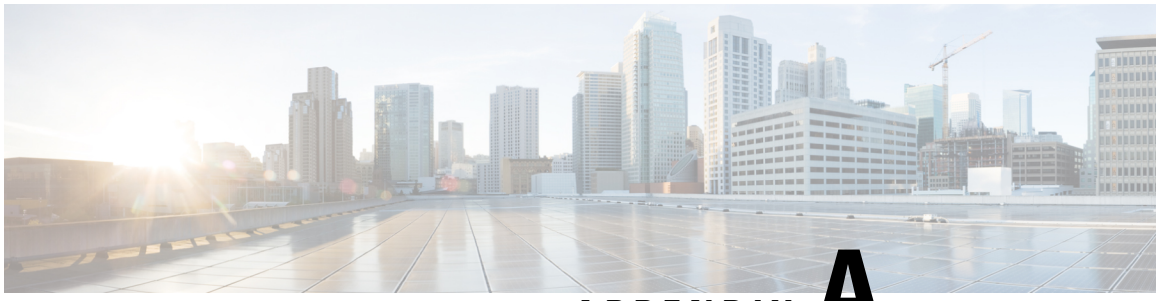
You must be an Admin user to perform this task.

Step 1 Choose **Analysis** > **Correlation** > **Status**.

Tip If you are using a custom workflow that does not include the table view of remediations, click **(switch workflow)** menu by the workflow title, then choose **Remediation Status**.

Step 2 You have the following options:

- To learn more about the columns that appear, see Remediation Status Table Fields, on page 2570.
- To sort and constrain the events, see Using Workflows, on page 2294.



APPENDIX A

Security, Internet Access, and Communication Ports

The following topics provide information on system security, internet access, and communication ports:

Security Requirements

To safeguard the Firepower Management Center, you should install it on a protected internal network. Although the FMC is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it (or any managed devices) from outside the firewall.

If the FMC and its managed devices reside on the same network, you can connect the management interfaces on the devices to the same protected internal network as the FMC. This allows you to securely control the devices from the FMC. You can also configure multiple management interfaces to allow the FMC to manage and isolate traffic from devices on other networks.

Regardless of how you deploy your appliances, inter-appliance communication is encrypted. However, you must still take steps to ensure that communications between appliances cannot be interrupted, blocked, or tampered with; for example, with a distributed denial of service (DDoS) or man-in-the-middle attack.

Cisco Clouds

The FMC communicates with resources in the Cisco cloud for the following features:

- **Advanced Malware Protection**

  The public cloud is configured by default; to make changes, see Change AMP Options, on page 1473.

- **URL filtering**

  For information, see:

  - URL Filtering Options, on page 1292

- Enable URL Filtering Using Category and Reputation, on page 1292

- **Integration with SecureX and Cisco SecureX threat response**

  For details, see the integration documents linked from:

  - Integrate with Cisco SecureX, on page 2257
  - Event Analysis with Cisco SecureX threat response, on page 2257

- **The proactive support feature**

  For information, see Cisco Support Diagnostics, on page 143.

- **Cisco Success Network**

  For information, see Cisco Success Network, on page 142.

Internet Access Requirements

By default, Firepower appliances are configured to connect to the internet on ports 443/tcp (HTTPS) and 80/tcp (HTTP). If you do not want your appliances to have direct access to the internet, you can configure a proxy server.

In most cases, it is the Firepower Management Center that accesses the internet. However, sometimes managed devices also access the internet. For example, if your malware protection configuration uses dynamic analysis, managed devices submit files directly to the Cisco Threat Grid cloud. Or, you may synchronize a device to an external NTP server.

Additionally, unless you disable web analytics tracking, your browser may contact Google web analytics servers to send non-personally-identifiable usage data to Cisco.

Tip If you are using AMP for Networks or AMP for Endpoints, your location can determine which AMP cloud resources the FMC accesses. The Required Server Addresses for Proper AMP Operations Troubleshooting TechNote lists the internet resources (including static IP addresses) required not only by Firepower appliances, but also by Cisco AMP components like connectors and private cloud appliances.

Both FMCs in a high availability pair should have internet access. Depending on the feature, sometimes both peers access the internet, and sometimes only the active peer does.

Table 335: Firepower Internet Access Requirements

Feature	Reason	FMC High Availability	Resource
AMP for Networks	Malware cloud lookups.	Both peers perform lookups.	See important tip above this table! cloud-sa.amp.cisco.com cloud-sa.eu.amp.cisco.com cloud-sa.apjc.amp.cisco.com cloud-sa-589592150.us-east-1.elb.amazonaws.com
	Download signature updates for file preclassification and local malware analysis.	Active peer downloads, syncs to standby.	updates.vrt.sourcefire.com amp.updates.vrt.sourcefire.com
	Submit files for dynamic analysis (managed devices). Query for dynamic analysis results (FMC).	Both peers query for dynamic analysis reports.	fmc.api.threatgrid.com fmc.api.threatgrid.eu
AMP for Endpoints integration	Receive malware events detected by AMP for Endpoints from the AMP cloud. Display malware events detected by the Firepower system in AMP for Endpoints. Use centralized file Block and Allow lists created in AMP for Endpoints to override dispositions from the AMP cloud.	Both peers receive events. You must also configure the cloud connection on both peers (configuration is not synced).	See Firepower information in https://www.cisco.com/c/en/us/support/docs/security/sourcefire-amp-appliances/118121-technote-sourcefire-00.html#anc5. See also the important tip above this table!
Security Intelligence	Download Security Intelligence feeds.	Active peer downloads, syncs to standby.	intelligence.sourcefire.com

Security, Internet Access, and Communication Ports

Feature	Reason	FMC High Availability	Resource
URL filtering	Download URL category and reputation data. Manually query (look up) URL category and reputation data. Query for uncategorized URLs.	Active FMC downloads, syncs to standby.	https://regsvc.sco.cisco.com https://est.sco.cisco.com https://updates-talos.sco.cisco.com http://updates.ironport.com IPV4: • 146.112.62.0/24 • 146.112.63.0/24 • 146.112.255.0/24 • 146.112.59.0/24 IPv6 • 2a04:e4c7:ffff::/48 • 2a04:e4c7:fffe::/48
Cisco Smart Licensing	Communicate with the Cisco Smart Software Manager.	Active peer communicates.	tools.cisco.com:443 www.cisco.com
Cisco Success Network	Transmit usage information and statistics.	Active peer communicates.	api-sse.cisco.com:8989 https://dex.sse.itd.cisco.com https://dex.eu.sse.itd.cisco.com
Cisco Support Diagnostics	Accepts authorized requests and transmits usage information and statistics.	Active peer communicates.	api-sse.cisco.com:8989
System updates	Download updates *directly* from Cisco to the FMC: • System software • Intrusion rules • Vulnerability database (VDB) • Geolocation database (GeoDB)	Update intrusion rules, the VDB, and the GeoDB on the active peer, which then syncs to the standby. Upgrade the system software independently on each peer. See the Cisco Firepower Management Center Upgrade Guide.	cisco.com sourcefire.com
Cisco Threat Response integration	See the *Firepower and Cisco Threat Response Integration Guide* available from https://www.cisco.com/c/en/us/support/security/defense-center/products-installation-and-configuration-guides-list.html.		

Feature	Reason	FMC High Availability	Resource
Time synchronization	Synchronize time in your deployment. Not supported with a proxy server.	Any appliance using an external NTP server must have internet access.	0.sourcefire.pool.ntp.org 1.sourcefire.pool.ntp.org 2.sourcefire.pool.ntp.org 3.sourcefire.pool.ntp.org
RSS feeds	Display the Cisco Threat Research Blog on the dashboard.	Any appliance displaying RSS feeds must have internet access.	blogs.cisco.com/talos cloud.google.com
Whois	Request whois information for an external host. Not supported with a proxy server.	Any appliance requesting whois information must have internet access.	The whois client tries to guess the right server to query. If it cannot guess, it uses: • NIC handles: whois.networksolutions.com • IPv4 addresses and network names: whois.arin.net

Communication Port Requirements

Firepower appliances communicate using a two-way, SSL-encrypted communication channel on port 8305/tcp. This port *must* remain open for basic intra-platform communication.

Other ports allow secure management, as well as access to external resources required by specific features. In general, feature-related ports remain closed until you enable or configure the associated feature. Do *not* change or close an open port until you understand how this action will affect your deployment.

Table 336: Firepower Communication Port Requirements

Port	Protocol/Feature	Platforms	Direction	Details
7/UDP	UDP/audit logging	FMC, classic	Outbound	Verify connectivity with the syslog server when configuring audit logging.
22/tcp	SSH	FMC Any device	Inbound	Secure remote connections to the appliance.
25/tcp	SMTP	FMC	Outbound	Send email notices and alerts.
53/tcp 53/udp	DNS	FMC Any device	Outbound	DNS
67/udp 68/udp	DHCP	FMC Any device	Outbound	DHCP
80/tcp	HTTP	FMC	Outbound	Display RSS feeds in the dashboard.

Security, Internet Access, and Communication Ports

Port	Protocol/Feature	Platforms	Direction	Details
80/tcp	HTTP	FMC	Outbound	Download or query URL category and reputation data (port 443 also required).
80/tcp	HTTP	FMC	Outbound	Download custom Security Intelligence feeds over HTTP.
123/udp	NTP	FMC Any device	Outbound	Synchronize time.
161/udp	SNMP	FMC Any device	Inbound	Allow access to MIBs via SNMP polling.
162/udp	SNMP	FMC Any device	Outbound	Send SNMP alerts to a remote trap server.
389/tcp 636/tcp	LDAP	FMC FTD	Outbound	Communicate with an LDAP server for external authentication. Obtain metadata for detected LDAP users (FMC only). Configurable.
443/tcp	HTTPS	FMC	Inbound	Access the web interface.
443/tcp	Remote access VPN (SSL/IPSec)	FTD	Inbound	Allow secure VPN connections to your network from remote users.
500/udp 4500/udp	Remote access VPN (IKEv2)	FTD	Inbound	Allow secure VPN connections to your network from remote users.
443/tcp	HTTPS	FMC FTD	Inbound	Communicate with integrated and third-party products using the Firepower REST API, including Cisco Terminal Services (TS) Agent.
443/tcp	HTTPS	FMC Any device	Outbound	Send and receive data from the internet. For details, see Internet Access Requirements, on page 2574.
443	HTTPS	FMC	Outbound	Communicate with the AMP cloud (public or private) See also information for port 32137.
443	HTTPS	FMC	Inbound and Outbound	Integrate with AMP for Endpoints
514/udp	Syslog (alerts)	FMC Any device	Outbound	Send alerts to a remote syslog server.

Security, Internet Access, and Communication Ports

Port	Protocol/Feature	Platforms	Direction	Details
623/udp	SOL/LOM	FMC	Inbound	Lights-Out Management (LOM) using a Serial Over LAN (SOL) connection.
885/tcp	Captive portal	Any device	Inbound	Communicate with a captive portal identity source.
1500/tcp 2000/tcp	Database access	FMC	Inbound	Allow read-only access to the event database by a third-party client.
1812/udp 1813/udp	RADIUS	FMC FTD	Outbound	Communicate with a RADIUS server for external authentication and accounting. Configurable.
3306/tcp	User Agent	FMC	Inbound	Communicate with User Agents.
5222/tcp	ISE	FMC	Outbound	Communicate with an ISE identity source.
6514/tcp	Syslog (audit events)	FMC NGIPSv ASA FirePOWER	Outbound	Send audit logs to a remote syslog server, when TLS is configured.
8302/tcp	eStreamer	FMC	Inbound	Communicate with an eStreamer client.
8305/tcp	Appliance communications	FMC Any device	Both	Securely communicate between appliances in a deployment. Configurable. If you change this port, you must change it for *all* appliances in the deployment. We recommend you keep the default.
8307/tcp	Host input client	FMC	Inbound	Communicate with a host input client.
8989/tcp	Cisco Success Network	FMC	Outbound	Transmit usage information and statistics.
8989/tcp	Cisco Support Diagnostics	FMC FTD	Both	Accepts authorized requests and transmits usage information and statistics.
32137/tcp	AMP for Networks	FMC	Outbound	Communicate with the Cisco AMP cloud. This is a legacy configuration. We recommend you use the default (443).

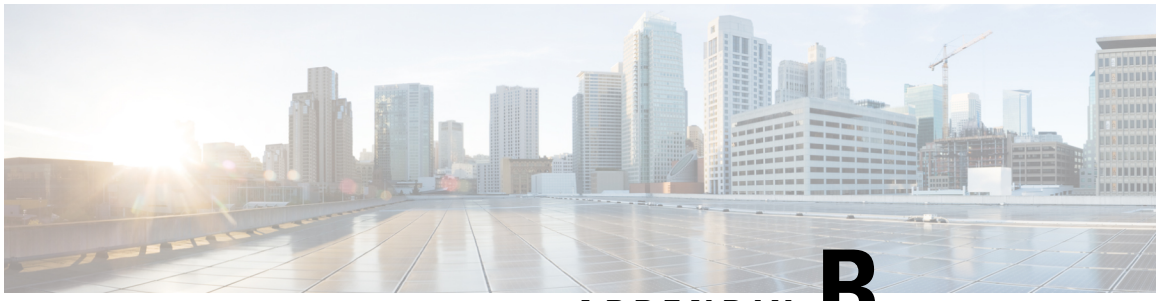
Security, Internet Access, and Communication Ports



APPENDIX B

Classic Device Command Line Reference

The Classic device CLI reference applies to:

- ASA FirePOWER
- NGIPSv

For other Firepower appliances:

- Firepower Threat Defense: See the Cisco Firepower Threat Defense Command Reference.
- Firepower Management Center: See Firepower Management Center Command Line Reference, on page 2631.

About the Classic Device CLI

After you log into a Classic device (ASA FirePOWER, NGIPSv) via the CLI (see Logging Into the CLI on ASA FirePOWER and NGIPSv Devices, on page 28), you can use the commands described in this appendix to view, configure, and troubleshoot your device.

Note that CLI commands are case-insensitive with the exception of parameters whose text is not part of the CLI framework, such as user names and search filters.

Related Topics

Firepower System User Interfaces, on page 23

Classic Device CLI Modes

The CLI encompasses four modes. The default mode, CLI Management, includes commands for navigating within the CLI itself. The remaining modes contain commands addressing three different areas of classic device functionality; the commands within these modes begin with the mode name: `system`, `show`, or `configure`.

When you enter a mode, the CLI prompt changes to reflect the current mode. For example, to display version information about system components, you can enter the full command at the standard CLI prompt:

```
> show version
```

If you have previously entered `show` mode, you can enter the command without the `show` keyword at the show mode CLI prompt:

```
show> version
```

Classic Device CLI Access Levels

Within each mode, the commands available to a user depend on the user's CLI access. When you create a user account, you can assign it one of the following CLI access levels:

- Basic — The user has read-only access and cannot run commands that impact system performance.
- Configuration — The user has read-write access and can run commands that impact system performance.
- None — The user is unable to log into the CLI.

On NGIPSv and ASA FirePOWER, you assign command line permissions using the CLI.

Classic Device CLI Management Commands

The CLI management commands provide the ability to interact with the CLI. These commands do not affect the operation of the device.

configure password

Allows the current user to change their password. After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Access

Basic

Syntax

```
configure password
```

Example

```
> configure password
Enter current password:
Enter new password:
Confirm new password:
```

exit

Moves the CLI context up to the next highest CLI context level. Issuing this command from the default mode logs the user out of the current CLI session, and is equivalent to issuing the `logout` CLI command.

Access

Basic

Syntax

```
exit
```

Example

```
configure network ipv4> exit
configure network>
```

expert

Invokes the Linux shell.

Caution We strongly recommend that you do not use the Linux shell unless directed by Cisco TAC or explicit instructions in the user documentation. For more information, see Firepower System User Accounts, on page 21.

Access

Configuration

Syntax

```
expert
```

Example

```
> expert
```

history

Displays the command line history for the current session.

Access

Basic

Syntax

```
history limit
```

where `limit` sets the size of the history list. To set the size to unlimited, enter zero.

Example

```
history 25
```

logout

Logs the current user out of the current CLI console session.

Access

Basic

Syntax

```
logout
```

Example

```
> logout
```

? (question mark)

Displays context-sensitive help for CLI commands and parameters. Use the question mark (`?`) command as follows:

- To display help for the commands that are available within the current CLI context, enter a question mark (`?`) at the command prompt.
- To display a list of the available commands that start with a particular character set, enter the abbreviated command immediately followed by a question mark (`?`).
- To display help for a command's legal arguments, enter a question mark (`?`) in place of an argument at the command prompt.

Note that the question mark (`?`) is not echoed back to the console.

Access

Basic

Syntax

```
?
```

```
abbreviated_command ?
command [arguments] ?
```

Example

```
> ?
```

Classic Device CLI Show Commands

Show commands provide information about the state of the device. These commands do not change the operational mode of the device and running them has minimal impact on system operation. Most show commands are available to all CLI users; however, only users with configuration CLI access can issue the `show user` command.

access-control-config

Displays the currently deployed access control configurations, including:

- Security Intelligence settings
- Names of any subpolicies the access control policy invokes
- Intrusion variable set data
- Logging settings
- Other advanced settings, including policy-level performance, preprocessing, and general settings

Also displays policy-related connection information, such as source and destination port data (including type and code for ICMP entries) and the number of connections that matched each access control rule (hit counts).

Access

Basic

Syntax

```
show access-control-config
```

Example

```
> show access-control-config
```

audit-log

Displays the audit log in reverse chronological order; the most recent audit log events are listed first.

Access

Basic

Syntax

```
show audit-log
```

Example

```
> show audit-log
```

audit_cert

Displays the current audit log client certificate.

Access

Basic

Syntax

```
show audit_cert
```

Example

```
> show audit_cert
```

cpu

Displays the current CPU usage statistics appropriate for the platform for all CPUs on the device.

- CPU — Processor number.
- %user — Percentage of CPU utilization that occurred while executing at the user level (application).
- %nice — Percentage of CPU utilization that occurred while executing at the user level with nice priority.
- %sys — Percentage of CPU utilization that occurred while executing at the system level (kernel). This does not include time spent servicing interrupts or softirqs. A softirq (software interrupt) is one of up to 32 enumerated software interrupts that can run on multiple CPUs at once.
- %iowait — Percentage of time that the CPUs were idle when the system had an outstanding disk I/O request.
- %irq — Percentage of time spent by the CPUs to service interrupts.
- %soft — Percentage of time spent by the CPUs to service softirqs.

- %steal — Percentage of time spent in involuntary wait by the virtual CPUs while the hypervisor was servicing another virtual processor.
- %guest — Percentage of time spent by the CPUs to run a virtual processor.
- %idle — Percentage of time that the CPUs were idle and the system did not have an outstanding disk I/O request.

Access

Basic

Syntax

```
show cpu [procnum]
```

where `procnum` is the number of the processor for which you want the utilization information displayed. Valid values are 0 to one less than the total number of processors on the system.

```
> show cpu
```

database Commands

The `show database` commands configure the device's management interface.

Access

Basic

processes

Displays a list of running database queries.

Access

Basic

Syntax

```
show database processes
```

Example

```
> show database processes
```

slow-query-log

Displays the slow query log of the database.

Access

Basic

Syntax

```
show database slow-query-log
```

Example

```
> show database slow-query-log
```

device-settings

Displays information about application bypass settings specific to the current device.

Access

Basic

Syntax

```
show device-settings
```

Example

```
> show device-settings
```

disk

Displays the current disk usage.

Access

Basic

Syntax

```
show disk
```

Example

```
> show disk
```

disk-manager

Displays detailed disk usage information for each part of the system, including silos, low watermarks, and high watermarks.

Access

Basic

Syntax

```
show disk-manager
```

Example

```
> show disk-manager
```

dns

Displays the current DNS server addresses and search domains.

Access

Basic

Syntax

```
show dns
```

Example

```
> show dns
```

hostname

Displays the device's host name and appliance UUID. If you edit the host name of a device using the CLI, confirm that the changes are reflected on the managing Firepower Management Center. In some cases, you may need to edit the device management settings manually.

Access

Basic

Syntax

```
show hostname
```

Example

```
> show hostname
```

hosts

Displays the contents of an ASA FirePOWER module's /etc/hosts file.

Access

Basic

Syntax

```
show hosts
```

Example

```
> show hosts
```

hyperthreading

Displays whether hyperthreading is enabled or disabled. This command is not available on ASA FirePOWER.

Access

Basic

Syntax

```
show hyperthreading
```

Example

```
> show hyperthreading
```

inline-sets

Displays configuration data for all inline security zones and associated interfaces. This command is not available on ASA FirePOWER.

Access

Basic

Syntax

```
show inline-sets
```

Example

```
> show inline-sets
```

interfaces

If no parameters are specified, displays a list of all configured interfaces. If a parameter is specified, displays detailed information about the specified interface.

Access

Basic

Syntax

```
show interfaces interface
```

where *interface* is the specific interface for which you want the detailed information.

Example

```
> show interfaces
```

ifconfig

Displays the interface configuration for an ASA FirePOWER module.

Access

Basic

Syntax

```
show ifconfig
```

Example

```
> show ifconfig
```

link-state

Displays type, link, speed of the ports on the device. This command is not available on ASA FirePOWER devices.

Access

Basic

Syntax

```
show link-state
```

Example

```
> show link-state
```

log-ips-connection

Displays whether the logging of connection events that are associated with logged intrusion events is enabled or disabled.

Access

Basic

Syntax

```
show log-ips-connection
```

Example

```
> show log-ips-connection
```

managers

Displays the configuration and communication status of the Firepower Management Center. Registration key and NAT ID are only displayed if registration is pending.

Access

Basic

Syntax

```
show managers
```

Example

```
> show managers
```

memory

Displays the total memory, the memory in use, and the available memory for the device.

Access

Basic

Syntax

```
show memory
```

Example

```
> show memory
```

model

Displays model information for the device.

Access

Basic

Syntax

```
show model
```

Example

```
> show model
```

netstat

Displays the active network connections for an ASA FirePOWER module.

Access

Basic

Syntax

```
show netstat
```

Example

```
> show netstat
```

network

Displays the IPv4 and IPv6 configuration of the management interface, its MAC address, and HTTP proxy address, port, and username if configured.

Access

Basic

Syntax

```
show network
```

Example

```
> show network
```

network-static-routes

Displays all configured network static routes and information about them, including interface, destination address, network mask, and gateway address.

Access

Basic

Syntax

```
show network-static-routes
```

Example

```
> show network-static-routes
```

ntp

Displays the ntp configuration.

Access

Basic

Syntax

```
show ntp
```

Example

```
> show ntp
```

perfstats

Displays performance statistics for the device.

Access

Basic

Syntax

```
show perfstats
```

Example

```
> show perfstats
```

process-tree

Displays processes currently running on the device, sorted in tree format by type.

Access

Basic

Syntax

```
show process-tree
```

Example

```
> show process-tree
```

processes

Displays processes currently running on the device, sorted by descending CPU usage.

Access

Basic

Syntax

```
show processes sort-flag filter
```

where *sort-flag* can be `-m` to sort by memory (descending order), `-u` to sort by username rather than the process name, or `verbose` to display the full name and path of the command. The *filter* parameter specifies the search term in the command or username by which results are filtered. The header row is still displayed.

Example

```
> show processes -u user1
```

route

Displays the routing information for an ASA FirePOWER module.

Access

Basic

Syntax

```
show route
```

Example

```
> show route
```

serial-number

Displays the chassis serial number. This command is not available on NGIPSv.

Access

Basic

Syntax

```
show serial-number
```

Example

```
> show serial-number
```

ssl-policy-config

Displays the currently deployed SSL policy configuration, including policy description, default logging settings, all enabled SSL rules and rule configurations, trusted CA certificates, and undecryptable traffic actions.

Access

Basic

Syntax

```
show ssl-policy-config
```

Example

```
> show ssl-policy-config
```

summary

Displays a summary of the most commonly used information (version, type, UUID, and so on) about the device. For more detailed information, see the following `show` commands: `version`, `interfaces`, `device-settings`, and `access-control-config`.

Access

Basic

Syntax

```
show summary
```

Example

```
> show summary
```

syslog

Displays the system log in reverse chronological order. You can optionally specify a filter to display specific records based on content and the number of records to display per page view (the default is 25).

Access

Basic

Syntax

```
show syslog ["filter" records_per_page]
```

where *filter* specifies a Grep-compatible search filter and *records_per_page* specifies the number of records to display with each page view. See Syntax for System Log Filters, on page 330 for more information on search filters.

Example

```
> show syslog "ssh" 20
```

The system displays the 20 most recent syslog records containing the string "ssh". To display the next 20 records, press Enter; to stop the display enter q.

time

Displays the current date and time in UTC and in the local time zone configured for the current user.

Access

Basic

Syntax

```
show time
```

Example

```
> show time
```

traffic-statistics

If no parameters are specified, displays details about bytes transmitted and received from all ports. If a port is specified, displays that information only for the specified port. You cannot specify a port for ASA FirePOWER modules; the system displays only the data plane interfaces.

Note In some situations the output of this command may show packet drops when, in point of fact, the device is not dropping traffic. Drop counters increase when malformed packets are received. A malformed packet may be missing certain information in the header or it may have failed a cyclical-redundancy check (CRC). Typically, common root causes of malformed packets are data link layer issues such as bad cables or a bad interface. The dropped packets are not logged. However, if the source is a reliable transport protocol such as TCP, the packets will be retransmitted.

Access

Basic

Syntax

```
show traffic-statistics port
```

where *port* is the specific port for which you want information.

Example

```
> show traffic-statistics s1p1
```

user

Applicable to NGIPSv only. Displays detailed configuration information for the specified user(s). The following values are displayed:

- Login — the login name
- UID — the numeric user ID
- Auth (`Local` or `Remote`) — how the user is authenticated
- Access (`Basic` or `Config`) — the user's privilege level
- Enabled (`Enabled` or `Disabled`) — whether the user is active
- Reset (`Yes` or `No`) — whether the user must change password at next login
- Exp (`Never` or a number) — the number of days until the user's password must be changed
- Warn (`N/A` or a number) — the number of days a user is given to change their password before it expires
- Str (`Yes` or `No`) — whether the user's password must meet strength checking criteria
- Lock (`Yes` or `No`) — whether the user's account has been locked due to too many login failures
- Max (`N/A` or a number) — the maximum number of failed logins before the user's account is locked

Access

Configuration

Syntax

```
show user username username username ...
```

where *username* specifies the name of the user and the usernames are space-separated.

Example

```
> show user jdoe
```

users

Displays detailed configuration information for all local users. The following values are displayed:

- Login — the login name
- UID — the numeric user ID
- Auth (`Local` or `Remote`) — how the user is authenticated
- Access (`Basic` or `Config`) — the user's privilege level
- Enabled (`Enabled` or `Disabled`) — whether the user is active
- Reset (`Yes` or `No`) — whether the user must change password at next login
- Exp (`Never` or a number) — the number of days until the user's password must be changed
- Warn (`N/A` or a number) — the number of days a user is given to change their password before it expires
- Str (`Yes` or `No`) — whether the user's password must meet strength checking criteria
- Lock (`Yes` or `No`) — whether the user's account is locked due to too many login failures
- Max (`N/A` or a number) — the maximum number of failed logins before the user's account is locked

Access

Configuration

Syntax

```
show users
```

Example

```
> show users
```

version

Displays the product version and build. If the `detail` parameter is specified, displays the versions of additional components.

Note The `detail` parameter is not available on ASA with FirePOWER Services.

Access

Basic

Syntax

```
show version [detail]
```

Example

```
> show version
```

vmware-tools

Indicates whether VMware Tools are currently enabled on a virtual device. This command is available only on NGIPSv.

VMware Tools is a suite of utilities intended to enhance the performance of the virtual machine. These utilities allow you to make full use of the convenient features of VMware products. The system supports the following plugins on all virtual appliances:

- guestInfo
- powerOps
- timeSync
- vmbackup

For more information about VMware Tools and the supported plugins, see the VMware website (http://www.vmware.com).

Access

Basic

Syntax

```
show vmware-tools
```

Example

```
> show vmware-tools
```

Classic Device CLI Configuration Commands

The configuration commands enable the user to configure and manage the system. These commands affect system operation; therefore, with the exception of Basic-level `configure password`, only users with configuration CLI access can issue these commands.

audit_cert Commands

The `configure audit_cert` commands configure the device's audit log client certificate for secure audit log streaming.

Access

Configuration

delete

Deletes the current client certificate for secure audit log streaming.

Syntax

```
configure audit_cert delete
```

Example

```
> configure audit_cert delete
```

import

Imports a client certificate for secure audit log streaming. After the user enters the command, the CLI prompts the user to provide either a client certificate and private key, or a certificate chain.

Syntax

```
configure audit_cert import
```

Example

```
> configure audit_cert import
***************Import Audit Client Certificate**************
```

```
1 Import Client Certificate and Private Key
2 Import Certificate Chain
0 Exit

************************************************************
Enter choice: 1
Enter your audit client certificate (PEM format) here:
-----BEGIN CERTIFICATE-----
MIIEoTCCA4mgAwIBAgICAR4wDQYJK0ZIhvcNaQALBWAugYICzAJBqNVBATYAiVT
   ...certificate details ...
Tx*FAhnXeUZ78hFepg1yHQMYWTkD7hCqmSN3UkAb1l0IoBcxTA==
-----END CERTIFICATE-----

Enter your private key (PEM format) here:
-----BEGIN RSA PRIVATE KEY-----

   ...private key details ...
nRI6QNkoumLUT9EvjF6bFoT3M6eDI7+NdDIhjVeOP*E4+hxEX50jM
-----END RSA PRIVATE KEY-----

Client certificate import succeed, exiting...
```

log-ips-connections

Enables or disables logging of connection events that are associated with logged intrusion events.

Access

Configuration

Syntax

```
configure log-ips-connections {enable | disable}
```

Example

```
> configure log-ips-connections disable
```

manager Commands

The `configure manager` commands configure the device's connection to its managing Firepower Management Center.

Access

Configuration

add

Configures the device to accept a connection from a managing Firepower Management Center. This command works only if the device is not actively managed.

A unique alphanumeric registration key is always required to register a device to a Firepower Management Center. In most cases, you must provide the hostname or the IP address along with the registration key. However, if the device and the Firepower Management Center are separated by a NAT device, you must enter a unique NAT ID, along with the registration key, and specify `DONTRESOLVE` instead of the hostname.

Syntax

```
configure manager add {hostname | IPv4_address | IPv6_address | DONTRESOLVE} regkey [nat_id]
```

where `{`hostname `|` IPv4_address `|` IPv6_address `|` `DONTRESOLVE}` specifies the DNS host name or IP address (IPv4 or IPv6) of the Firepower Management Center that manages this device. If the Firepower Management Center is not directly addressable, use `DONTRESOLVE`. If you use`DONTRESOLVE`, nat_id is required. regkey is the unique alphanumeric registration key required to register a device to the Firepower Management Center. nat_id is an optional alphanumeric string used during the registration process between the Firepower Management Center and the device. It is required if the hostname is set to `DONTRESOLVE`.

Example

```
> configure manager add DONTRESOLVE abc123 efg456
```

delete

Removes the Firepower Management Center's connection information from the device. This command only works if the device is not actively managed.

Syntax

```
configure manager delete
```

Example

```
> configure manager delete
```

network Commands

The `configure network` commands configure the device's management interface.

Access

Configuration

dns searchdomains

Replaces the current list of DNS search domains with the list specified in the command.

Syntax

```
configure network dns searchdomains {searchlist}
```

where `searchlist` is a comma-separated list of domains.

Example

```
> configure network dns searchdomains foo.bar.com,bar.com
```

dns servers

Replaces the current list of DNS servers with the list specified in the command.

Syntax

```
configure nework dns servers {dnslist}
```

where dnslist is a comma-separated list of DNS servers.

Example

```
> configure network dns servers 10.123.1.10,10.124.1.10
```

hostname

Sets the hostname for the device.

Syntax

```
configure network hostname {name}
```

where name is the new hostname.

Example

```
> configure network hostname sfrocks
```

http-proxy

On NGIPSv devices, configures an HTTP proxy. After issuing the command, the CLI prompts the user for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Use this command on NGIPSv to configure an HTTP proxy server so the virtual device can submit files to the AMP cloud for dynamic analysis.

Syntax

The proxy password can use only alphanumeric characters.

```
configure network http-proxy
```

Example

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address:
Enter HTTP Proxy Port:
Use Proxy Authentication? (y/n) [n]:
Enter Proxy Username:
Enter Proxy Password:
Confirm Proxy Password:
```

http-proxy-disable

On NGIPSv devices, deletes any HTTP proxy configuration.

Syntax

```
configure network http-proxy-disable
```

Example

```
> configure network http-proxy-disable
Are you sure that you wish to delete the current
http-proxy configuration? (y/n):
```

ipv4 delete

Disables the IPv4 configuration of the device's management interface.

Syntax

```
configure network ipv4 delete
```

Example

```
> configure network ipv4 delete eth1
```

ipv4 dhcp

Sets the IPv4 configuration of the device's management interface to DHCP. The management interface communicates with the DHCP server to obtain its configuration information.

Syntax

```
configure network ipv4 dhcp [management_interface]
```

where *management_interface* is the management interface ID. DHCP is supported only on the default management interface, so you do not need to use this argument.

Example

```
> configure network ipv4 dhcp
```

ipv4 manual

Manually configures the IPv4 configuration of the device's management interface.

Syntax

```
configure network ipv4 manual ipaddr netmask [gw]
```

where *ipaddr* is the IP address, *netmask* is the subnet mask, and *gw* is the IPv4 address of the default gateway.

Example

```
> configure network ipv4 manual 10.123.1.10 255.255.0.0 10.123.1.1
```

ipv6 delete

Disables the IPv6 configuration of the device's management interface.

Syntax

```
configure network ipv6 delete
```

Example

```
> configure network ipv6 delete
```

ipv6 dhcp

Sets the IPv6 configuration of the device's management interface to DHCP. The management interface communicates with the DHCP server to obtain its configuration information.

Syntax

```
configure network ipv6 dhcp [management_interface]
```

where *management_interface* is the management interface ID. DHCP is supported only on the default management interface, so you do not need to use this argument.

Example

```
> configure network ipv6 dhcp
```

ipv6 manual

Manually configures the IPv6 configuration of the device's management interface.

Syntax

```
configure network ipv6 manual ip6addr/ip6prefix [ip6gw]
```

where *ip6addr*/*ip6prefix* is the IP address and prefix length and *ip6gw* is the IPv6 address of the default gateway.

Example

```
> configure network ipv6 manual 2001:DB8:3ffe:1900:4545:3:200:f8ff:fe21:67cf 64
```

ipv6 router

Sets the IPv6 configuration of the device's management interface to Router. The management interface communicates with the IPv6 router to obtain its configuration information.

Syntax

```
configure network ipv6 router
```

Example

```
> configure network ipv6 router
```

management-interface tcpport

Changes the value of the TCP port for management.

Syntax

```
configure network management-interface tcpport port
```

where *port* is the management port value you want to configure.

Example

```
> configure network management-interface tcpport 8500
```

management-port

Sets the value of the device's TCP management port.

Syntax

```
configure network management-port number
```

where *number* is the management port value you want to configure.

Example

```
> configure network management-port 8500
```

static-routes ipv4 add

Adds an IPv4 static route for the specified management interface.

Syntax

```
configure network static-routes ipv4
add interface destination netmask gateway
```

where interface is the management interface, destination is the destination IP address, netmask is the network mask address, and gateway is the gateway address you want to add.

Example

```
> configure network static-routes ipv4
add eth1 10.115.24.0 255.255.255.0 10.115.9.2
```

static-routes ipv4 delete

Deletes an IPv4 static route for the specified management interface.

Syntax

```
configure network static-routes ipv4
delete interface destination netmask gateway
```

where interface is the management interface, destination is the destination IP address, netmask is the network mask address, and gateway is the gateway address you want to delete.

Example

```
> configure network static-routes ipv4
delete eth1 10.115.24.0 255.255.255.0 10.115.9.2
```

static-routes ipv6 add

Adds an IPv6 static route for the specified management interface.

Syntax

```
configure network static-routes ipv6
add interface destination prefix gateway
```

where interface is the management interface, destination is the destination IP address, prefix is the IPv6 prefix length, and gateway is the gateway address you want to add.

Example

```
> configure network static-routes ipv6
add eth1 2001:DB8:3ffe:1900:4545:3:200: f8ff:fe21:67cf 64
```

static-routes ipv6 delete

Deletes an IPv6 static route for the specified management interface.

Syntax

```
configure network static-routes ipv6
delete interface destination prefix gateway
```

where interface is the management interface, destination is the destination IP address, prefix is the IPv6 prefix length, and gateway is the gateway address you want to delete.

Example

```
> configure network static-routes ipv6
delete eth1 2001:DB8:3ffe:1900:4545:3:200:f8ff: fe21:67cf 64
```

password

Allows the current user to change their password. After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Access

Basic

Syntax

```
configure password
```

Example

```
> configure password
Enter current password:
Enter new password:
Confirm new password:
```

user Commands

Applicable only to NGIPSv, the `configure user` commands manage the device's local user database.

Access

Configuration

access

Modifies the access level of the specified user. This command takes effect the next time the specified user logs in.

Syntax

```
configure user access username [basic | config]
```

where *username* specifies the name of the user for which you want to modify access, `basic` indicates basic access, and `config` indicates configuration access.

Example

```
> configure user access jdoe basic
```

add

Creates a new user with the specified name and access level. This command prompts for the user's password.

Syntax

```
configure user add username [basic | config]
```

where username specifies the name of the new user, `basic` indicates basic access, and `config` indicates configuration access.

Example

```
> configure user add jdoe basic
Enter new password for user jdoe:
Confirm new password for user jdoe:
```

aging

Forces the expiration of the user's password.

Syntax

```
configure user aging username max_days warn_days
```

where `username` specifies the name of the user, `max_days` indicates the maximum number of days that the password is valid, and`warn_days` indicates the number of days that the user is given to change the password before it expires.

Example

```
> configure user aging jdoe 100 3
```

delete

Deletes the user and the user's home directory.

Syntax

```
configure user delete username
```

where `username` specifies the name of the user.

Example

```
> configure user delete jdoe
```

disable

Disables the user. Disabled users cannot login.

Syntax

```
configure user disable username
```

where `username` specifies the name of the user.

Example

```
> configure user disable jdoe
```

enable

Enables the user.

Syntax

```
configure user enable username
```

where username specifies the name of the user.

Example

```
> configure user enable jdoe
```

forcereset

Forces the user to change their password the next time they login. When the user logs in and changes the password, strength checking is automatically enabled.

Syntax

```
configure user forcereset username
```

where *username* specifies the name of the user.

Example

```
> configure user forcereset jdoe
```

maxfailedlogins

Sets the maximum number of failed logins for the specified user.

Syntax

```
configure user maxfailedlogins username number
```

where *username* specifies the name of the user, and *number* specifies the maximum number of failed logins.

Example

```
> configure user maxfailedlogins jdoe 3
```

minpasswdlen

Sets the minimum number of characters a user password must contain.

Syntax

```
configure user minpasswdlen username number
```

Where *username* specifies the name of the user account, and *number* specifies the minimum number of characters the password for that account must contain (ranging from 1 to 127).

Example

```
> configure user minpasswdlen jdoe 13
```

password

Sets the user's password. This command prompts for the user's password.

Syntax

```
configure user password username
```

where *username* specifies the name of the user.

Example

```
> configure user pasword jdoe
Enter new password for user jdoe:
Confirm new password for user jdoe:
```

strengthcheck

Enables or disables the strength requirement for a user's password. When a user's password expires or if the configure user forcereset command is used, this requirement is automatically enabled the next time the user logs in.

Syntax

```
configure user strengthcheck username {enable | disable}
```

where *username* specifies the name of the user, `enable` sets the requirement for the specified users password, and `disable` removes the requirement for the specified user's password.

Example

```
> configure user strengthcheck jdoe enable
```

unlock

Unlocks a user that has exceeded the maximum number of failed logins.

Syntax

```
configure user unlock username
```

where *username* specifies the name of the user.

Example

```
> configure user unlock jdoe
```

user-agent

Allows you to change the password used to authenticate the Cisco Firepower User Agent Version 2.5 or later with ASA with FirePOWER Services.

Password rules:

- 8 character minimum length
- 127 character maximum length
- Must contain at least 1 digit
- Must contain at least 1 letter

  Must contain at least one special character not including **?$=** (question mark, dollar sign, equal sign)
- Cannot contain **\, ', "** (backslash, single quote, double quote)
- Cannot be dictionary word
- Cannot include non-printable ASCII characters / extended ASCII characters
- Must have no more than 2 repeating characters

Syntax

```
configure user-agent
```

Example

```
> configure user-agent
Enter new password for user-agent:
Confirm new password for user-agent:
The user-agent password has been changed.
```

vmware-tools

Enables or disables VMware Tools functionality on NGIPSv. This command is available only on NGIPSv.

VMware Tools is a suite of utilities intended to enhance the performance of the virtual machine. These utilities allow you to make full use of the convenient features of VMware products. The system supports the following plugins on all virtual appliances:

- guestInfo

- powerOps
- timeSync
- vmbackup

For more information about VMware Tools and the supported plugins, see the VMware website (http://www.vmware.com).

Access

Basic

Syntax

```
configure vmware-tools [enable | disable]
```

Example

```
> configure vmware-tools enable
```

Classic Device CLI System Commands

The system commands enable the user to manage system-wide files and access control settings. Only users with configuration CLI access can issue commands in system mode.

access-control Commands

The `system access-control` commands enable the user to manage the access control configuration on the device.

Access

Configuration

archive

Saves the currently deployed access control policy as a text file on `/var/common`.

Syntax

```
system access-control archive
```

Example

```
> system access-control archive
```

clear-rule-counts

Resets the access control rule hit count to 0.

Syntax

```
system access-control clear-rule-counts
```

Example

```
> system access-control clear-rule-counts
```

rollback

Reverts the system to the previously deployed access control configuration.

Syntax

```
system access-control rollback
```

Example

```
> system access-control rollback
```

compliance Commands

The `compliance` commands display and configure the device's security certifications compliance mode.

Caution After you enable this setting, you cannot disable it. If you need to do so, contact Support for assistance.

Access

Configuration

enable cc

Configures the device's security certifications compliance to Common Criteria (CC) mode.

Caution After you enable this setting, you cannot disable it. If you need to do so, contact Support for assistance.

Syntax

```
system compliance enable cc
```

Example

```
> system compliance enable cc
```

enable ucapl

Configures the device’s security certifications compliance to Unified Capabilities Approved Products List (UCAPL) mode.

Caution After you enable this setting, you cannot disable it. If you need to do so, contact Support for assistance.

Syntax

```
system compliance enable ucapl
```

Example

```
> system compliance enable ucapl
```

show

Displays the device's current security certifications compliance mode.

Syntax

```
system compliance show
```

Example

```
> system compliance show
```

disable-http-user-cert

Disables the requirement that the browser present a valid client certificate.

Access

Configuration

Syntax

```
system disable-http-user-cert
```

Example

```
> system disable-http-user-cert
```

file Commands

The `system file` commands enable the user to manage the files in the common directory on the device.

Access

Configuration

copy

Uses FTP to transfer files to a remote location on the host using the login username. The local files must be located in the common directory.

Syntax

```
system file copy hostname username path filenames filenames ...
```

where `hostname` specifies the name or ip address of the target remote host, `username` specifies the name of the user on the remote host, `path` specifies the destination path on the remote host, and `filenames` specifies the local files to transfer; the file names are space-separated.

Example

```
> system file copy sfrocks jdoe /pub *
```

delete

Removes the specified files from the common directory.

Syntax

```
system file delete filenames filenames ...
```

where `filenames` specifies the files to delete; the file names are space-separated.

Example

```
> system file delete *
```

list

If no file names are specified, displays the modification time, size, and file name for all the files in the common directory. If file names are specified, displays the modification time, size, and file name for files that match the specified file names.

Syntax

```
system file list filenames
```

where *filenames* specifies the files to display; the file names are space-separated.

Example

```
> system file list
```

secure-copy

Uses SCP to transfer files to a remote location on the host using the login username. The local files must be located in the `/var/common` directory.

Syntax

```
system file secure-copy hostname username path filenames filenames ...
```

where *hostname* specifies the name or ip address of the target remote host, *username* specifies the name of the user on the remote host, *path* specifies the destination path on the remote host, and *filenames* specifies the local files to transfer; the file names are space-separated.

Example

```
> system file secure-copy 10.123.31.1 jdoe /tmp *
```

generate-troubleshoot

Generates troubleshooting data for analysis by Cisco.

Caution Generating troubleshooting files for lower-memory devices can trigger Automatic Application Bypass (AAB) when AAB is enabled, At a minimum, triggering AAB restarts the Snort process, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 379 for more information. In some such cases, triggering AAB can render the device temporarily inoperable. If inoperability persists, contact Cisco Technical Assistance Center (TAC), who can propose a solution appropriate to your deployment. Susceptible devices include ASA 5508-X, 5516-X, and 5525-X; NGIPSv.

Access

Configuration

Syntax

```
system generate-troubleshoot option1 optionN
```

Where options are one or more of the following, space-separated:

- `ALL`: Run all of the following options.
- `SNT`: Snort Performance and Configuration
- `PER`: Hardware Performance and Logs
- `SYS`: System Configuration, Policy, and Logs
- `DES`: Detection Configuration, Policy, and Logs
- `NET`: Interface and Network Related Data
- `VDB`: Discover, Awareness, VDB Data, and Logs
- `UPG`: Upgrade Data and Logs
- `DBO`: All Database Data
- `LOG`: All Log Data
- `NMP`: Network Map Information

Example

```
> system generate-troubleshoot VDB NMP
starting /usr/local/sf/bin/sf_troubleshoot.pl…
Please, be patient. This may take several minutes.
The troubleshoot options codes specified are VDB,NMP.
Getting filenames from [usr/local/sf/etc/db_updates/index]
Getting filenames from [usr/local/sf/etc/db_updates/base-6.2.3]
Troubleshooting information successfully created at
/var/common/results-06-14-2018—222027.tar.gz
```

ldapsearch

Enables the user to perform a query of the specified LDAP server. Note that all parameters are required.

Access

Configuration

Syntax

```
system ldapsearch host port baseDN userDN basefilter
```

where host specifies the LDAP server domain, port specifies the LDAP server port, baseDN specifies the DN (distinguished name) that you want to search under, userDN specifies the DN of the user who binds to the LDAP directory, and basefilter specifies the record or records you want to search for.

Example

```
> system ldapsearch ldap.example.com 389 cn=users,

dc=example,dc=com cn=user1,cn=users,dc=example,dc=com, cn=user2
```

lockdown

Removes the `expert` command and access to the Linux shell on the device.

Caution This command is irreversible without a hotfix from Support. Use with care.

Access

Configuration

Syntax

```
system lockdown
```

Example

```
> system lockdown
```

reboot

Reboots the device.

Access

Configuration

Syntax

```
system reboot
```

Example

```
> system reboot
```

restart

Restarts the device application.

Access

Configuration

Syntax

```
system restart
```

Example

```
> system restart
```

support Commands

The `system support` commands enable the user to manage special SSL ClientHello processing on the device.

Access

Configuration

ssl-client-hello-display

Displays the current settings for processing the ClientHello message during an SSL handshake. For a description of these settings, see the `ssl-client-hello-enabled` and `ssl-client-hello-tuning` commands.

Access

Basic

Syntax

```
system support ssl-client-hello-display
```

Example

```
> system support ssl-client-hello-display
```

ssl-client-hello-enabled

Controls special processing of the ClientHello message during the SSL handshake.

Caution Use these commands *only* if advised to do so by Cisco TAC.

Access

Configuration

Syntax

```
system support ssl-client-hello-enabled setting {true | false}
```

Possible *setting* values are:

feature
Controls all special handling of ClientHello messages.

curves
Controls stripping of elliptic curves that the Firepower System does not support:

- `true` (enabled)—The system strips any unsupported elliptic curves from the ClientHello message, increasing the likelihood of traffic decryption. You must also enable the `extensions` setting.
- `false` (disabled)—The system retains unsupported elliptic curves in the ClientHello message, decreasing the likelihood of traffic decryption.

ciphers
Controls stripping of cipher suites that the Firepower System does not support:

- `true` (enabled)—The system strips unsupported cipher suites from ClientHello messages, increasing the likelihood of traffic decryption.
- `false` (disabled)—The system retains unsupported cipher suites in ClientHello messages. This decreases the likelihood of traffic decryption and can result in a number of `Unsupported` or `Unknown Cipher` errors in the SSL Flow Error field of associated connection events.

extensions
Controls stripping of TLS extensions that prevent decryption:

- `true` (enabled)—The system identifies TLS extensions that prevent decryption and strips them from the ClientHello message. This value is required if you want to enable **curves**, **session_ticket**, and **alpn**.
- `false` (disabled)—The system retains all TLS extensions in the ClientHello message. This decreases the likelihood of traffic decryptions and can result in `Unknown Session` errors in the SSL Flow Error field of associated connection events.

session_ticket
Controls processing of the SessionTicket extension in ClientHello messages. If the system can match a SessionTicket value in an incoming ClientHello message to cached session data, it can resume the session without the client and server performing the full SSL handshake.

- `true` (enabled)—The system strips unrecognized SessionTicket values from the ClientHello message. This increases the likelihood of traffic decryption for the resumed session. You must also enable the `extensions` setting.
- `false` (disabled)—The system retains all SessionTicket values in the ClientHello message. This decreases the likelihood of traffic decryption and can result in `Uncached Session` errors in the SSL Flow Error field of associated connection events.

session_id
Controls processing of the Session Identifier element in ClientHello messages. If the system can match the Session Identifier in an incoming ClientHello message to cached session data, it can resume the session without the client and server performing the full SSL handshake.

- `true` (enabled)—The system strips unrecognized Session Identifier values from the ClientHello message. This increases the likelihood of traffic decryption for the resumed session.
- `false` (disabled)—The system retains all Session Identifier values in the ClientHello message. This decreases the likelihood of traffic decryption and can result in `Uncached Session` errors in the SSL Flow Error field of associated connection events.

alpn
Controls stripping of ALPN protocol values that cannot be decrypted, specifically, the SPDY and HTTP2 protocols:

- `true` (enabled)—The system prevents the client from establishing SPDY or HTTP2 sessions, increasing the likelihood of traffic decryption and inspection. You must also enable the `extensions` setting.
- `false` (disabled)—The system allows the client to establish SPDY or HTTP2 sessions with the server, decreasing the likelihood of traffic decryption and inspection.

compression
Controls stripping of TLS compression requests from ClientHello messages:

- `true` (enabled)—The system prevents the client from establishing a TLS compressed session with the server.
- `false` (disabled)—The system allows the client to establish a TLS compressed session with the server. This prevents traffic decryption for the session and can result in `Compression Used` errors in the SSL Flow Error field of associated connection events.

tls13_downgrade
Determines whether or not the FTD attempts to downgrade to TLS 1.2 a server request for a TLS 1.3 connection. FTD does not currently support TLS 1.3.

- `true` (enabled)—The system attempts to downgrade a TLS 1.3 connection to TLS 1.2.
- `false` (disabled)—The system does not attempt to downgrade, resulting in a failed connection.

aggressive_tls13_downgrade
Use this command *only* if advised to do so by Cisco TAC.

Example

```
> system support ssl-client-hello-enabled feature false
```

ssl-client-hello-force-reset

Resets the configurable settings for ClientHello message processing to default values. The system does not require user confirmation before proceeding.

Caution Do **not** use this command unless you are directed to do so by Support.

Access

Configuration

Syntax

```
system support ssl-client-hello-force-reset
```

Example

```
> system support ssl-client-hello-force-reset
```

ssl-client-hello-reset

Resets the configurable settings for ClientHello message processing to default values. The system requires user confirmation before proceeding.

Caution Do **not** use this command unless you are directed to do so by Support.

Access

Configuration

Syntax

```
system support ssl-client-hello-reset
```

Example

```
> system support ssl-client-hello-reset
```

ssl-client-hello-tuning

Allows you to refine how the managed device modifies ClientHello messages during SSL handshakes. This command tunes the default lists of cipher suites, elliptic curves, and extensions that the system allows in ClientHello messages. This command only adds entries to or removes entries from the default lists of allowed values. It does not overwrite the default lists.

Caution Do **not** use this command unless you are directed to do so by Support.

Access

Configuration

Syntax

```
system support ssl-client-hello-tuning setting value
```

The *value* element supports a comma-delimited list of values. Possible values for the *setting* and *value* elements include:

Setting	**System Action**	***Value***
`ciphers_allow`	Allows the specified cipher suites in ClientHello messages. If you use this command, the system retains the specified cipher suites in any ClientHello messages it modifies.	Obtain individual cipher suite numbers from the IANA website: https://www.iana.org/assignments/tls-parameters/tls-parameters.xhtml#tls-parameters-4 IANA provides values in hexadecimal. Convert them to decimal for use in this command.
`ciphers_remove`	Disallows the specified cipher suites in ClientHello messages. If you use this command, the system strips the specified cipher suites from any ClientHello message it modifies.	
`curves_allow`	Allows the specified elliptic curves in ClientHello messages. If you use this command, the system retains the specified elliptic curves in any ClientHello message it modifies.	Obtain curve numbers from the IANA website: https://www.iana.org/assignments/tls-parameters/tls-parameters.xhtml#tls-parameters-8
`curves_remove`	Disallows the specified elliptic curves in ClientHello messages. If you use this command, the system strips the specified elliptic curves from any ClientHello message it modifies.	
`extensions_allow`	Allows the specified extensions in ClientHello messages. If you use this command, the system retains the specified extensions in any ClientHello message it modifies.	Obtain extension numbers from the IANA website: https://www.iana.org/assignments/tls-extensiontype-values/tls-extensiontype-values.xhtml
`extensions_remove`	Disallows the specified elliptic curves in ClientHello messages. The system strips the specified extensions from any ClientHello message it modifies. By default, the system disallows extensions 22, 23, and 30032.	

Example

```
> system support ssl-client-hello-tuning ciphers_allow 4,7,16,22
```

shutdown

Shuts down the device. This command is not available on ASA FirePOWER modules.

Access

Configuration

Syntax

```
system shutdown
```

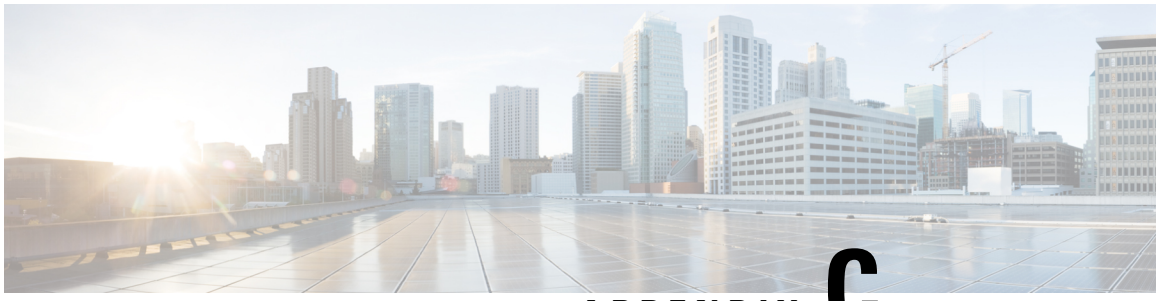
Example

```
> system shutdown
```

History for Classic Device CLI

Feature	Version	Details
Deprecated CLI commands	6.5	The following CLI commands are useful only on devices that are not supported with Version 6.5: • **show alarms** • **show arp-tables** • **show bypass** and **config bypass** • **show high-availability** and **configure high-availability** (all commands) • **show fan-status** • **show fastpath-rules** • **show gui** and **configure gui** • **show http-cert-expire-date** • **show lcd** and **configure lcd** • **show link-aggregation** (all commands) • **show mpls-depth** and **configure mpls-depth** • **show nat** and **system nat** (all commands) • **show network-modules** • **show portstats** • **show power-supply-status** • **show routing-table** • **show stacking** and **configure stacking** • **show virtual-routers** • **show virtual-switches** • **show vpn** (all commands) • **configure network management-interface** (all commands to enable and disable management and event channels) • **system renew-http-cert** Although the CLI will display help for these deprecated commands if you use the ? (question mark) command, they are not described in this guide or the online help. For detailed information on these commands, see the CLI appendix in the Firepower Management Center Configuration Guide that corresponds to your device version.

Feature	Version	Details
Configure the Firepower User Agent password.	6.5	You can change the password for the user agent version 2.5 and later using the **configure user-agent** command.
HTTPS Certificates	6.3	The default HTTPS server certificate provided with the system now expires in three years. If your appliance uses a default certificate that was generated before you upgraded to Version 6.3, the certificate will expire 20 years from when it was first generated. If you are using the default HTTPS server certificate the system now provides the ability to renew it. New classic CLI commands: **show http-cert-expire date**, **`system renew-http-cert`** Supported platforms: Physical FMCs
Classic CLI command `system lockdown-sensor` syntax.	6.3	The **system lockown-sensor** command in the Classic CLI is now **system lockdown**.



APPENDIX C

Firepower Management Center Command Line Reference

This reference explains the command line interface (CLI) for the Firepower Management Center.

Note For Classic devices (ASA FirePOWER, NGIPSv), see Classic Device Command Line Reference, on page 2581.

Note For Firepower Threat Defense, see the Cisco Firepower Threat Defense Command Reference.

About the Firepower Management Center CLI

When you use SSH to log into the Firepower Management Center, you access the CLI. Although we strongly discourage it, you can then access the Linux shell using the `expert` command .

Caution We strongly recommend that you do not access the Linux shell unless directed by Cisco TAC or explicit instructions in the Firepower user documentation.

Caution Users with Linux shell access can obtain root privileges, which can present a security risk. For system security reasons, we strongly recommend:

- If you establish external authentication, make sure that you restrict the list of users with Linux shell access appropriately.
- Do not establish Linux shell users in addition to the pre-defined `admin` user.

You can use the commands described in this appendix to view and troubleshoot your Firepower Management Center, as well as perform limited configuration operations.

Firepower Management Center CLI Modes

The CLI encompasses four modes. The default mode, CLI Management, includes commands for navigating within the CLI itself. The remaining modes contain commands addressing three different areas of Firepower Management Center functionality; the commands within these modes begin with the mode name: `system`, `show`, or `configure`.

When you enter a mode, the CLI prompt changes to reflect the current mode. For example, to display version information about system components, you can enter the full command at the standard CLI prompt:

```
> show version
```

If you have previously entered `show` mode, you can enter the command without the `show` keyword at the show mode CLI prompt:

```
show> version
```

Firepower Management Center CLI Management Commands

The CLI management commands provide the ability to interact with the CLI. These commands do not affect the operation of the device.

exit

Moves the CLI context up to the next highest CLI context level. Issuing this command from the default mode logs the user out of the current CLI session.

Syntax

```
exit
```

Example

```
system> exit
>
```

expert

Invokes the Linux shell.

Syntax

```
expert
```

Example

```
> expert
```

? (question mark)

Displays context-sensitive help for CLI commands and parameters. Use the question mark (?) command as follows:

- To display help for the commands that are available within the current CLI context, enter a question mark (?) at the command prompt.
- To display a list of the available commands that start with a particular character set, enter the abbreviated command immediately followed by a question mark (?).
- To display help for a command's legal arguments, enter a question mark (?) in place of an argument at the command prompt.

Note that the question mark (?) is not echoed back to the console.

Syntax

```
?
abbreviated_command ?
command [arguments] ?
```

Example

```
> ?
```

Firepower Management Center CLI Show Commands

Show commands provide information about the state of the appliance. These commands do not change the operational mode of the appliance and running them has minimal impact on system operation.

version

Displays the product version and build.

Syntax

```
show version
```

Example

```
> show version
```

Firepower Management Center CLI Configuration Commands

The configuration commands enable the user to configure and manage the system. These commands affect system operation.

password

Allows the current CLI user to change their password.

Caution For system security reasons, we strongly recommend that you do not establish Linux shell users in addition to the pre-defined **admin** on any appliance.

After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Syntax

```
configure password
```

Example

```
> configure password
Changing password for admin.
(current) UNIX password:
New UNIX password:
Retype new UNIX password:
passwd: password updated successfully
```

user-agent

Allows you to change the password used to authenticate the Cisco Firepower User Agent Version 2.5 or later with the Firepower Management Center.

Password rules:

- 8 character minimum length
- 127 character maximum length

- Must contain at least 1 digit
- Must contain at least 1 letter

  Must contain at least one special character not including **?$=** (question mark, dollar sign, equal sign)
- Cannot contain **\, ', "** (backslash, single quote, double quote)
- Cannot be dictionary word
- Cannot include non-printable ASCII characters / extended ASCII characters
- Must have no more than 2 repeating characters

Syntax

```
configure user-agent
```

Example

```
> configure user-agent
Enter new password for user-agent:
Confirm new password for user-agent:
The user-agent password has been changed.
```

Firepower Management Center CLI System Commands

The system commands enable the user to manage system-wide files and access control settings.

generate-troubleshoot

Generates troubleshooting data for analysis by Cisco.

Syntax

```
system generate-troubleshoot option1 optionN
```

Where options are one or more of the following, space-separated:

- `ALL`: Run all of the following options.
- `SNT`: Snort Performance and Configuration
- `PER`: Hardware Performance and Logs
- `SYS`: System Configuration, Policy, and Logs
- `DES`: Detection Configuration, Policy, and Logs
- `NET`: Interface and Network Related Data
- `VDB`: Discover, Awareness, VDB Data, and Logs

- `UPG`: Upgrade Data and Logs
- `DBO`: All Database Data
- `LOG`: All Log Data
- `NMP`: Network Map Information

Example

```
> system generate-troubleshoot VDB NMP
starting /usr/local/sf/bin/sf_troubleshoot.pl…
Please, be patient. This may take several minutes.
The troubleshoot options codes specified are VDB,NMP.
Getting filenames from [usr/local/sf/etc/db_updates/index]
Getting filenames from [usr/local/sf/etc/db_updates/base-6.2.3]
Troubleshooting information successfully created at
/var/common/results-06-14-2018—222027.tar.gz
```

lockdown

Removes the `expert` command and access to the Linux shell on the device.

Caution This command is irreversible without a hotfix from Support. Use with care.

Syntax

```
system lockdown
```

Example

```
> system lockdown
```

reboot

Reboots the appliance.

Syntax

```
system reboot
```

Example

```
> system reboot
```

restart

Restarts the appliance application.

Syntax

```
system restart
```

Example

```
> system restart
```

shutdown

Shuts down the appliance.

Syntax

```
system shutdown
```

Example

```
> system shutdown
```

History for the Firepower Management Center CLI

Feature	Version	Details
Automatic CLI access for the FMC	6.5	When you use SSH to log into the FMC, you automatically access the CLI. Although strongly discouraged, you can then use the CLI `expert` command to access the Linux shell. **Note** This feature deprecates the Version 6.3 ability to enable and disable CLI access for the FMC. As a consequence of deprecating this option, the virtual FMC no longer displays the **System** > **Configuration** > **Console Configuration** page, which still appears on physical FMCs.
Configure the Firepower User Agent password.	6.5	You can change the password for the user agent version 2.5 and later using the **configure user-agent** command.

Feature	Version	Details
Ability to enable and disable CLI access for the FMC	6.3	New/Modified screens: New check box available to administrators in FMC web interface: **Enable CLI Access** on the **System** > **Configuration** > **Console Configuration** page. • Checked: Logging into the FMC using SSH accesses the CLI. • Unchecked: Logging into FMC using SSH accesses the Linux shell. This is the default state for fresh Version 6.3 installations as well as upgrades to Version 6.3 from a previous release. Supported platforms: FMC
FMC CLI	6.3	Feature introduced. Initally supports the following commands: • `exit` • `expert` • `?` • `show version` • `configure password` • `system generate-troubleshoot` • `system lockdown` • `system reboot` • `system restart` • `system shutdown` Supported platforms: FMC
